Recap from Last Lecture

- Synchronization primitives:
  - Locks
  - Semaphores
  - Monitors

Recap from Last Lecture

- Synchronization **primitives**:
  - Locks
  - Semaphores
  - Monitors
- 2 fundamental synchronization problems:
  - Producers-Consumers
  - Readers-Writers

Another Synchronization Problem

- It's lunch time at the Department of Philosophy

Another Synchronization Problem

- It's lunch time at the Department of Philosophy
- 5 philosophers sitting at a round table

Another Synchronization Problem

- It's lunch time at the Department of Philosophy
- 5 philosophers sitting at a round table
- Each philosopher has one chopstick on her/his left and one on her/his right (i.e., 5 chopsticks in total)

Another Synchronization Problem

- It's lunch time at the Department of Philosophy
- 5 philosophers sitting at a round table
- Each philosopher has one chopstick on her/his left and one on her/his right (i.e., 5 chopsticks in total)
- 2 things philosophers are good at ☺:
  - Eating
  - Thinking

The Dining Philosophers

- Thinking means do nothing (just kidding, but you get the idea!)

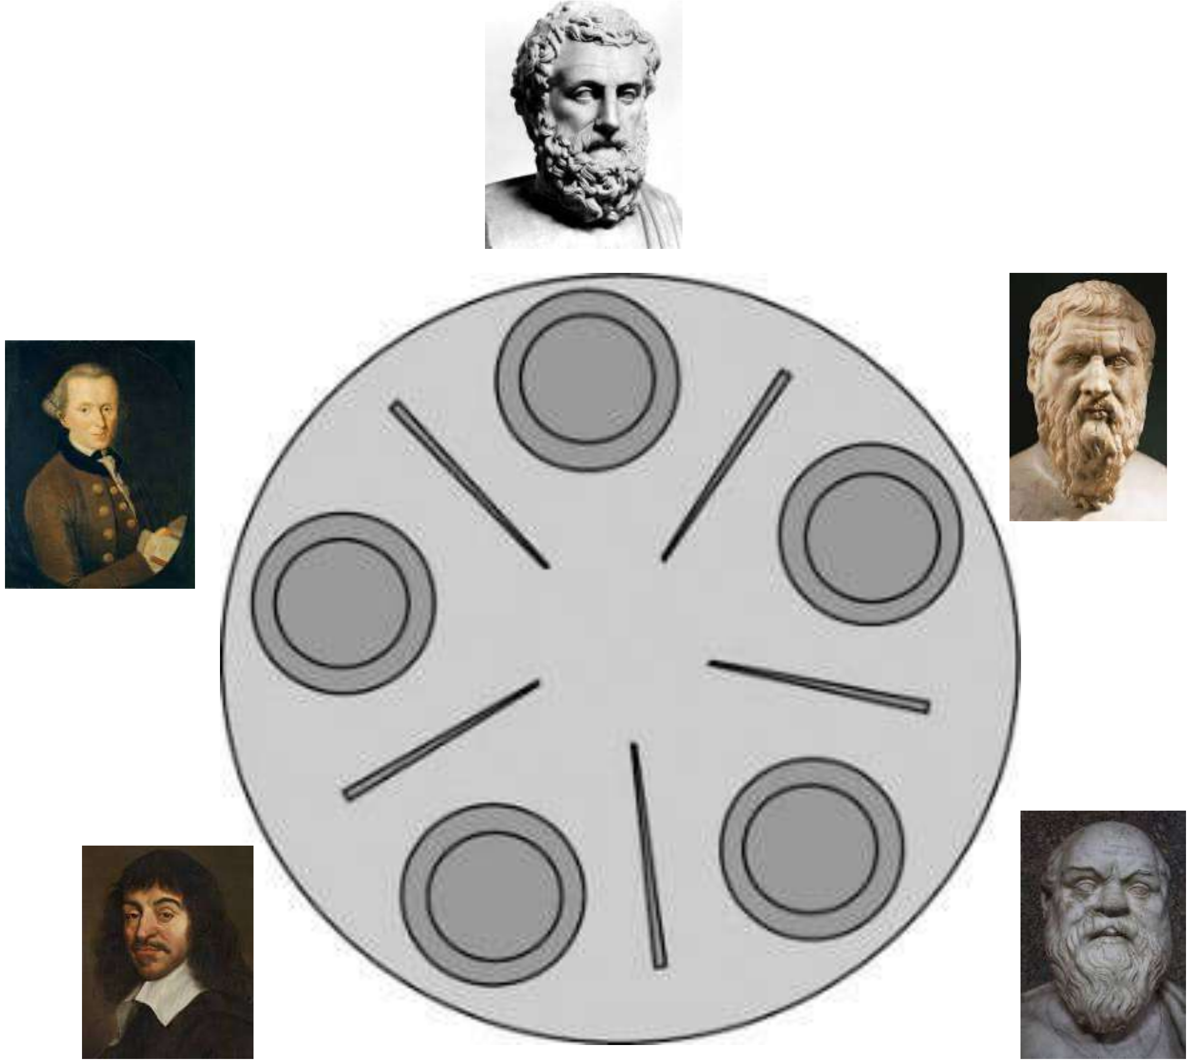
The Dining Philosophers

- Thinking means do nothing (just kidding, but you get the idea!)
- Eating means acquiring 2 chopsticks, but how?
  - Try to pick up the two closest chopsticks (the left and the right ones)
  - Block if a neighbour has already picked up a chopstick

The Dining Philosophers

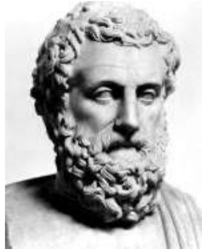
- Thinking means do nothing (just kidding, but you get the idea!)
- Eating means acquiring 2 chopsticks, but how?
  - Try to pick up the two closest chopsticks (the left and the right ones)
  - Block if a neighbour has already picked up a chopstick
- After eating, put down both chopsticks and go back thinking!

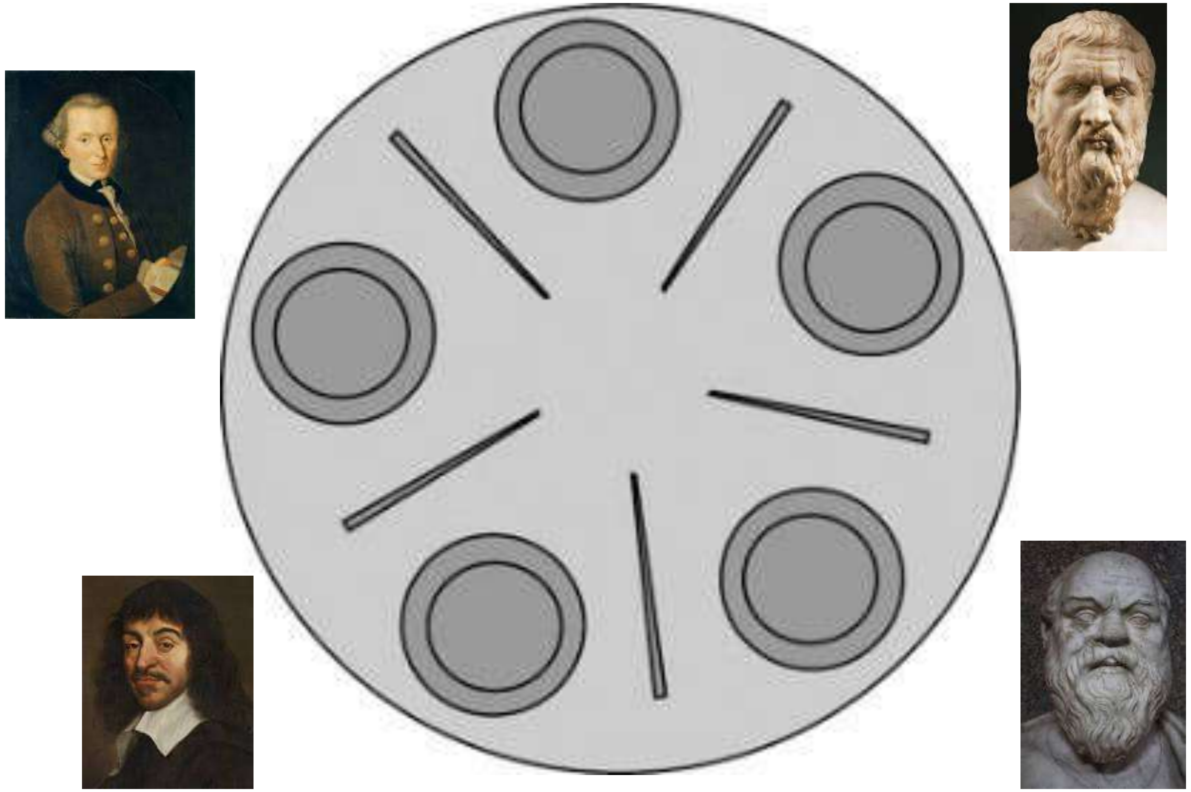
The Dining Philosophers



The Dining Philosophers

How to make them not starving?





The Dining Philosophers

What's the trivial solution to the dining philosophers problem?

The Dining Philosophers

What's the trivial solution to the dining philosophers problem?

Have a "global" lock which allows a single philosopher to pick both chopsticks

The Dining Philosophers

What's the trivial solution to the dining philosophers problem?

Have a "global" lock which allows a single philosopher to pick both chopsticks

Very inefficient! Only one philosopher at a time can eat

The Dining Philosophers

What's the trivial solution to the dining philosophers problem?

Have a "global" lock which allows a single philosopher to pick both chopsticks

Very inefficient! Only one philosopher at a time can eat

We still want some concurrency here ☺

The Dining Philosophers: Solution 1

```
Semaphore chopsticks[5];

while(True) {
    chopsticks[i].wait();        // wait on the left chopstick
    chopsticks[(i+1)%5].wait(); // wait on the right chopstick

    eat();

    chopsticks[i].signal();        // signal on the left chopstick
    chopsticks[(i+1)%5].signal(); // signal on the right chopstick

    think();
}
```

The Dining Philosophers: Solution 1

```
Semaphore chopsticks[5];

while(True) {
    chopsticks[i].wait();         // wait on the left chopstick
    chopsticks[(i+1)%5].wait(); // wait on the right chopstick

    eat();

    chopsticks[i].signal();         // signal on the left chopstick
    chopsticks[(i+1)%5].signal(); // signal on the right chopstick

    think();
}
```

Is this solution correct?

The Dining Philosophers: Solution 1

```
Semaphore chopsticks[5];

while(True) {
    chopsticks[i].wait();        // wait on the left chopstick
    chopsticks[(i+1)%5].wait(); // wait on the right chopstick

    eat();

    chopsticks[i].signal();        // signal on the left chopstick
    chopsticks[(i+1)%5].signal(); // signal on the right chopstick

    think();
}
```

Is this solution correct?

No! Possible **deadlock** if all philosophers take the left chopstick

The Dining Philosophers: Solution II (monitors)

Deadlock may occur because each philosopher ends up with just one chopstick (rather than two)

The Dining Philosophers: Solution II (monitors)

Deadlock may occur because each philosopher ends up with just one chopstick (rather than two)

Idea: Before picking one chopstick be sure also the second one is available, otherwise wait for the neighbour to finish

The Dining Philosophers: Solution II (monitors)

Deadlock may occur because each philosopher ends up with just one chopstick (rather than two)

Idea: Before picking one chopstick be sure also the second one is available, otherwise wait for the neighbour to finish

Testing if either one of the two neighbours of a given philosopher is currently eating (condition variables)

The Dining Philosophers: Solution II (monitors)

Deadlock may occur because each philosopher ends up with just one chopstick (rather than two)

Idea: Before picking one chopstick be sure also the second one is available, otherwise wait for the neighbour to finish

Testing if either one of the two neighbours of a given philosopher is currently eating (condition variables)

Never gonna pick a single chopstick!

The Dining Philosophers: Solution II (monitors)

```
class Philosopher {
    enum Status {
        THINKING,
        HUNGRY,
        EATING
    }
    Status state;

    public Philosopher() {
        this.state = THINKING;
    }
}
```

```
class DiningPhilosophers {
    Philosopher[5] philosophers;

    public DiningPhilosopers() {
        for(int i=0; i < 5; ++i) {
            this.philosophers[i] = new Philosopher();
        }
    }
    // continue implementation -------->
```

```
void canEat(int i) {
    State state = this.philosophers[i].state;
    State left = this.philosophers[[(i-1)%5].state;
    State right = this.philosophers[[(i+1)%5].state;
    if(left != EATING && right != EATING && state == HUNGRY) {
        this.philosophers[i].state = EATING;
        this.philosophers[i].notify();
    }
}
```

```
void synchronized pickup(int i) {
    this.philosophers[i].state = HUNGRY;
    canEat(i);
    if(this.philosophers[i].state != EATING) {
        this.philosophers[i].wait();
    }
}
```

```
void synchronized putdown(int i) {
    this.philosophers[i].state = THINKING;
    canEat((i - 1) % 5); // left neighbour
    canEat((i + 1) % 5); // right neighbour
}
```

Real-World Examples

- The problems we have seen so far are interesting because they identify some patterns which are very common in practice

Real-World Examples

- The problems we have seen so far are interesting because they identify some patterns which are very common in practice
  - Producer-Consumer
    - Audio/Video player embedded in a web browser: shared data buffer + network and render threads

    - Audio/Video player embedded in a web browser: shared data buffer + network and render threads
  - Reader-Writer
    - Banking system: read vs. update account balances
  - Dining Philosophers
    - Lock on multiple resources: e.g., travel reservation (hotel, airline, car rental databases)

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

What is Deadlock?

"When two trains approach each other at a crossing, both shall come to a full stop and neither shall start up again until the other has gone."

Kansas legislation early 1900's

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

A starts first

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Acquires printer and context switch

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

B takes over

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Acquires disk and context switch

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

A executes again and blocks

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

B executes again and blocks

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

A waits B to release the disk

What is Deadlock?

Intuitively, a condition where two or more threads are waiting for an event that can only be generated by the very same threads

Thread A

```
printer.wait();
disk.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

Thread B

```
disk.wait();
printer.wait();

// copy from disk to printer

printer.signal();
disk.signal();
```

B waits A to release the printer

Deadlock: Terminology

- **Deadlock:** it can occur when multiple threads compete for a finite number of resources

Deadlock: Terminology

- **Deadlock:** it can occur when multiple threads compete for a finite number of resources
- **Deadlock detection:** finds instances of deadlocks and tries to recover

Deadlock: Terminology

- **Deadlock:** it can occur when multiple threads compete for a finite number of resources
- **Deadlock detection:** finds instances of deadlocks and tries to recover
- **Deadlock prevention (offline):** imposes restrictions/rules on how to write deadlock-free programs

Deadlock: Terminology

- **Deadlock:** it can occur when multiple threads compete for a finite number of resources
- **Deadlock detection:** finds instances of deadlocks and tries to recover
- **Deadlock prevention (offline):** imposes restrictions/rules on how to write deadlock-free programs
- **Deadlock avoidance (online):** runtime support checks resource requests made by threads to avoid deadlocks

Deadlock vs. Starvation

- Not to be confused with each other!

Deadlock vs. Starvation

- Not to be confused with each other!
- Related terms but each one refers to a specific situation

Deadlock vs. Starvation

- Not to be confused with each other!
- Related terms but each one refers to a specific situation
- Starvation occurs when a thread waits indefinitely for some resource but other threads are actually making progress using that resource

Deadlock vs. Starvation

- Not to be confused with each other!
- Related terms but each one refers to a specific situation
- Starvation occurs when a thread waits indefinitely for some resource but other threads are actually making progress using that resource
- The main difference with deadlock is that the system is not completely stuck!

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

Necessary Conditions for Deadlock

- Deadlock *can* happen if *all* the 4 conditions below hold

Necessary Conditions for Deadlock

- Deadlock *can* happen if *all* the 4 conditions below hold
  - Mutual Exclusion → at least one thread must hold a non-sharable resource (only one thread holds the resource)

Necessary Conditions for Deadlock

- Deadlock *can* happen if *all* the 4 conditions below hold
  - Mutual Exclusion → at least one thread must hold a non-sharable resource (only one thread holds the resource)
  - Hold and Wait → at least one thread is holding a non-sharable resource and is waiting for other resource(s) to become available (another thread holds the resource(s))

Necessary Conditions for Deadlock

- Deadlock *can* happen if *all* the 4 conditions below hold
  - Mutual Exclusion → at least one thread must hold a non-sharable resource (only one thread holds the resource)
  - Hold and Wait → at least one thread is holding a non-sharable resource and is waiting for other resource(s) to become available (another thread holds the resource(s))
  - No Preemption → a thread can only release a resource voluntarily; neither another thread nor the OS can force it to release the resource

Necessary Conditions for Deadlock

- Deadlock *can* happen if *all* the 4 conditions below hold
  - Mutual Exclusion → at least one thread must hold a non-sharable resource (only one thread holds the resource)
  - Hold and Wait → at least one thread is holding a non-sharable resource and is waiting for other resource(s) to become available (another thread holds the resource(s))
  - No Preemption → a thread can only release a resource voluntarily; neither another thread nor the OS can force it to release the resource
  - Circular Wait → a set of waiting threads $t_1, \ldots, t_n$ where t_i is waiting on $t_{(i+1)\%n}$

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

Deadlock Detection: Resource Allocation Graph

- We define a directed graph $G=(V, E)$ where:

Deadlock Detection: Resource Allocation Graph

- We define a directed graph $G=(V, E)$ where:
  - V is the set of vertices representing both resources $\{r_1, \ldots, r_m\}$ and threads $\{t_1, \ldots, t_n\}$

Deadlock Detection: Resource Allocation Graph

- We define a directed graph $G=(V, E)$ where:
  - V is the set of vertices representing both resources $\{r_1, \ldots, r_m\}$ and threads $\{t_1, \ldots, t_n\}$
  - E is the set of edges between resources and threads

Deadlock Detection: Resource Allocation Graph

- We define a directed graph $G=(V, E)$ where:
  - V is the set of vertices representing both resources $\{r_1, \ldots, r_m\}$ and threads $\{t_1, \ldots, t_n\}$
  - E is the set of edges between resources and threads
- Edges can be of 2 types:

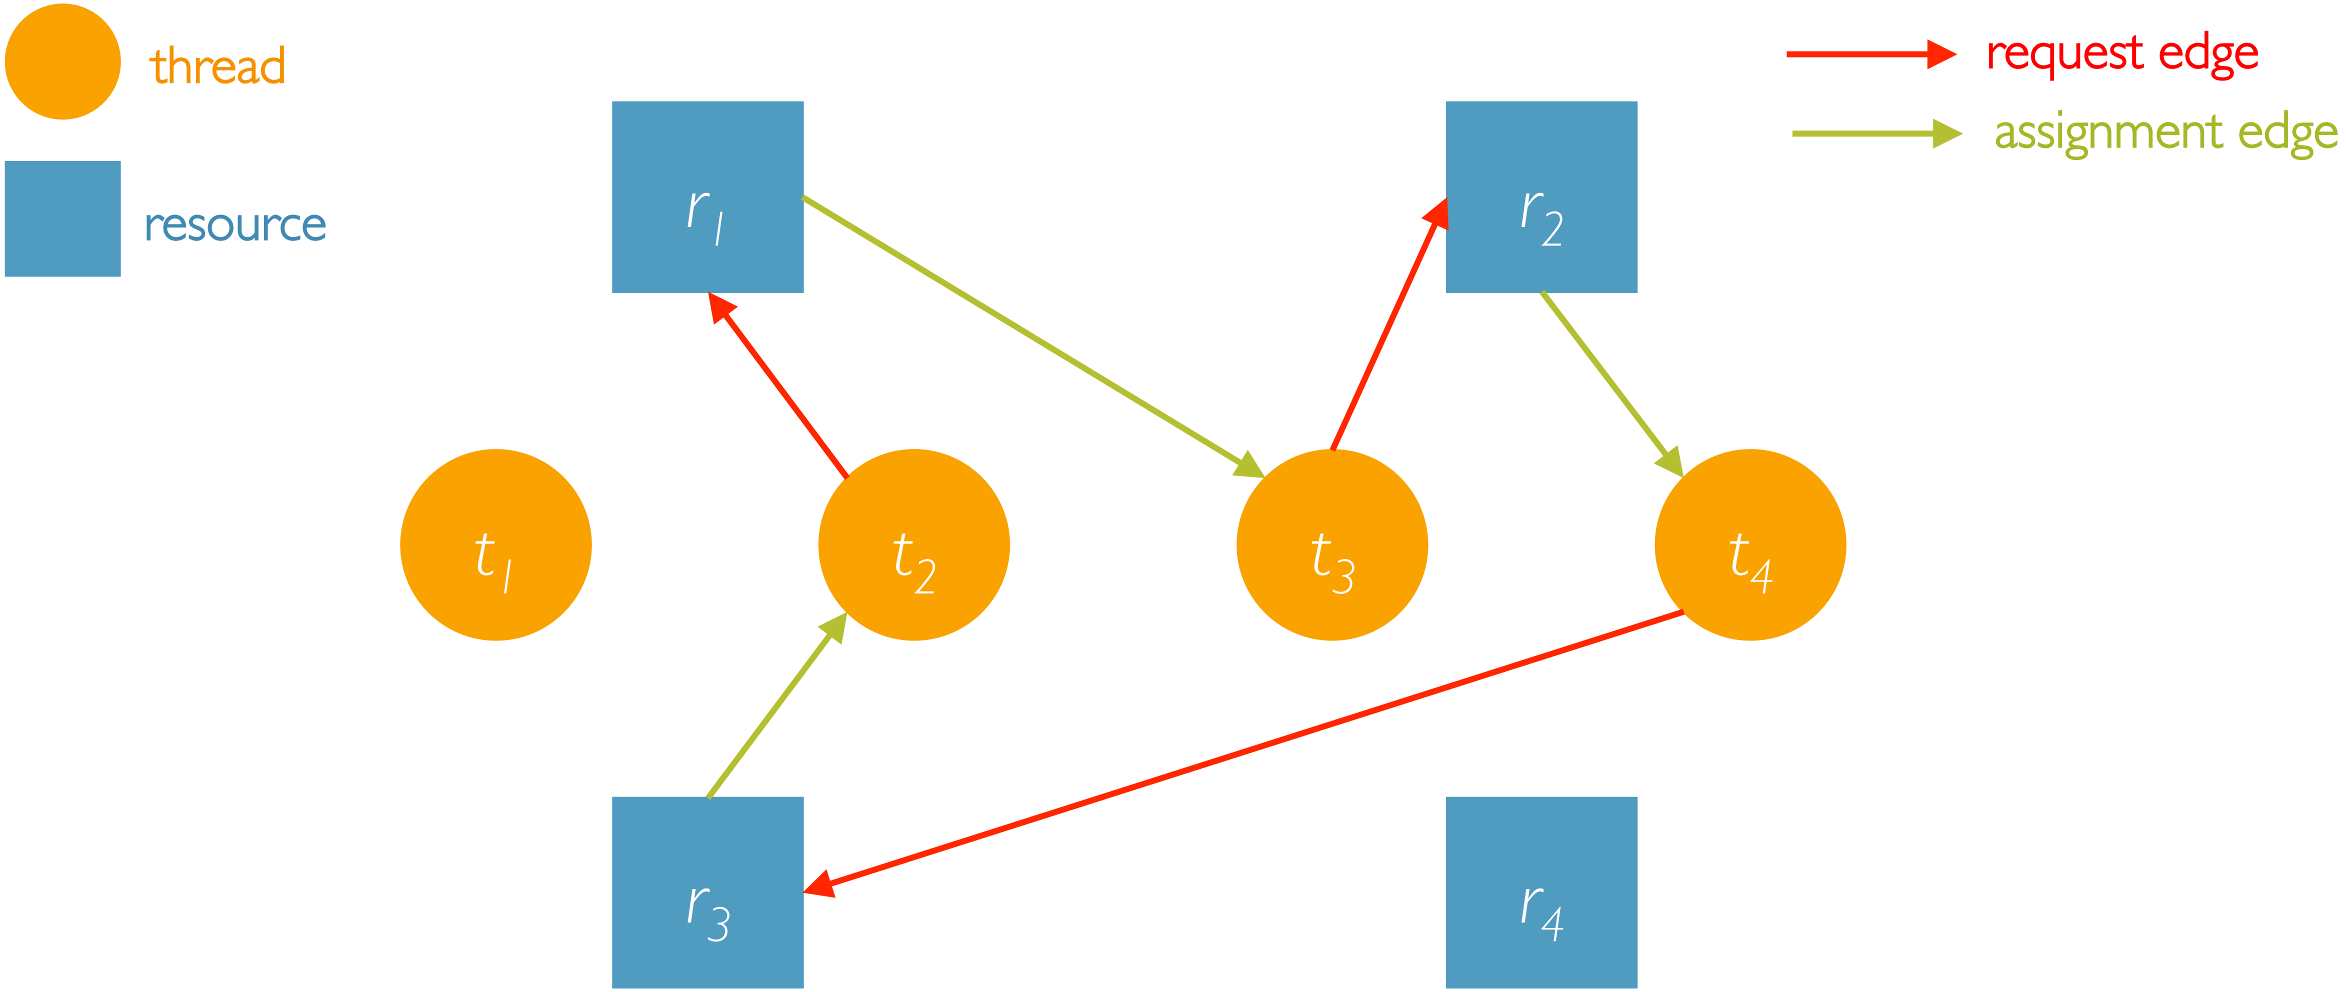
Deadlock Detection: Resource Allocation Graph

- We define a **directed graph** $G=(V, E)$ where:
  - V is the set of **vertices** representing both **resources** $\{r_1, \ldots, r_m\}$ and **threads** $\{t_1, \ldots, t_n\}$
  - E is the set of **edges** between resources and threads
- Edges can be of **2 types**:
  - **Request Edge** → a directed edge (t_i, r_j) indicates that t_i has requested r_j, but not yet acquired

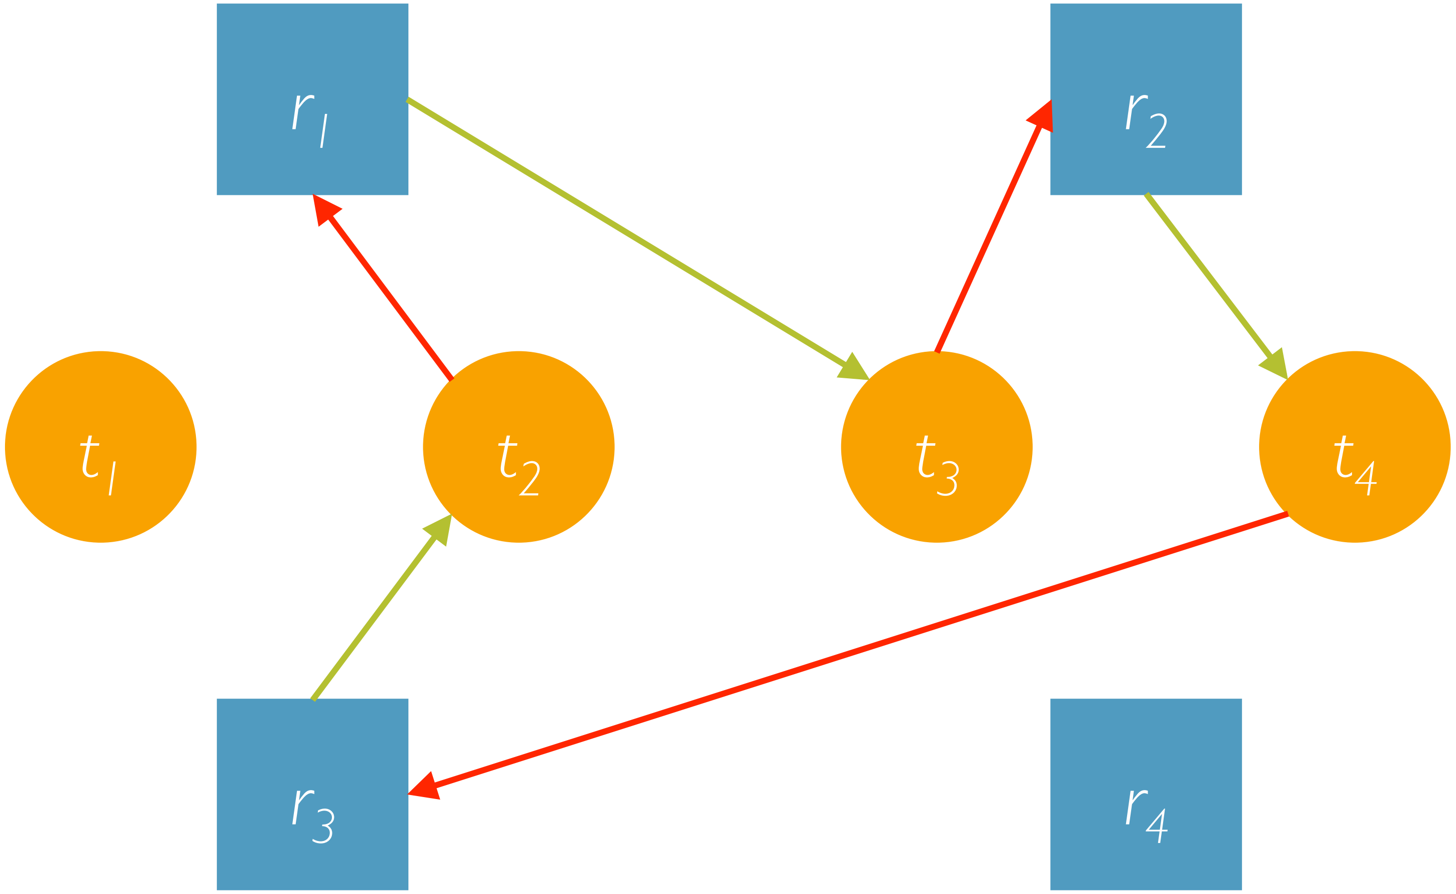
Deadlock Detection: Resource Allocation Graph

- We define a directed graph $G=(V, E)$ where:
  - V is the set of vertices representing both resources $\{r_1, \ldots, r_m\}$ and threads $\{t_1, \ldots, t_n\}$
  - E is the set of edges between resources and threads
- Edges can be of 2 types:
  - Request Edge → a directed edge (t_i, r_j) indicates that t_i has requested r_j, but not yet acquired
  - Assignment Edge → a directed edge (r_j, t_i) indicates that the OS has allocated r_j to t_i

Deadlock Detection: Resource Allocation Graph

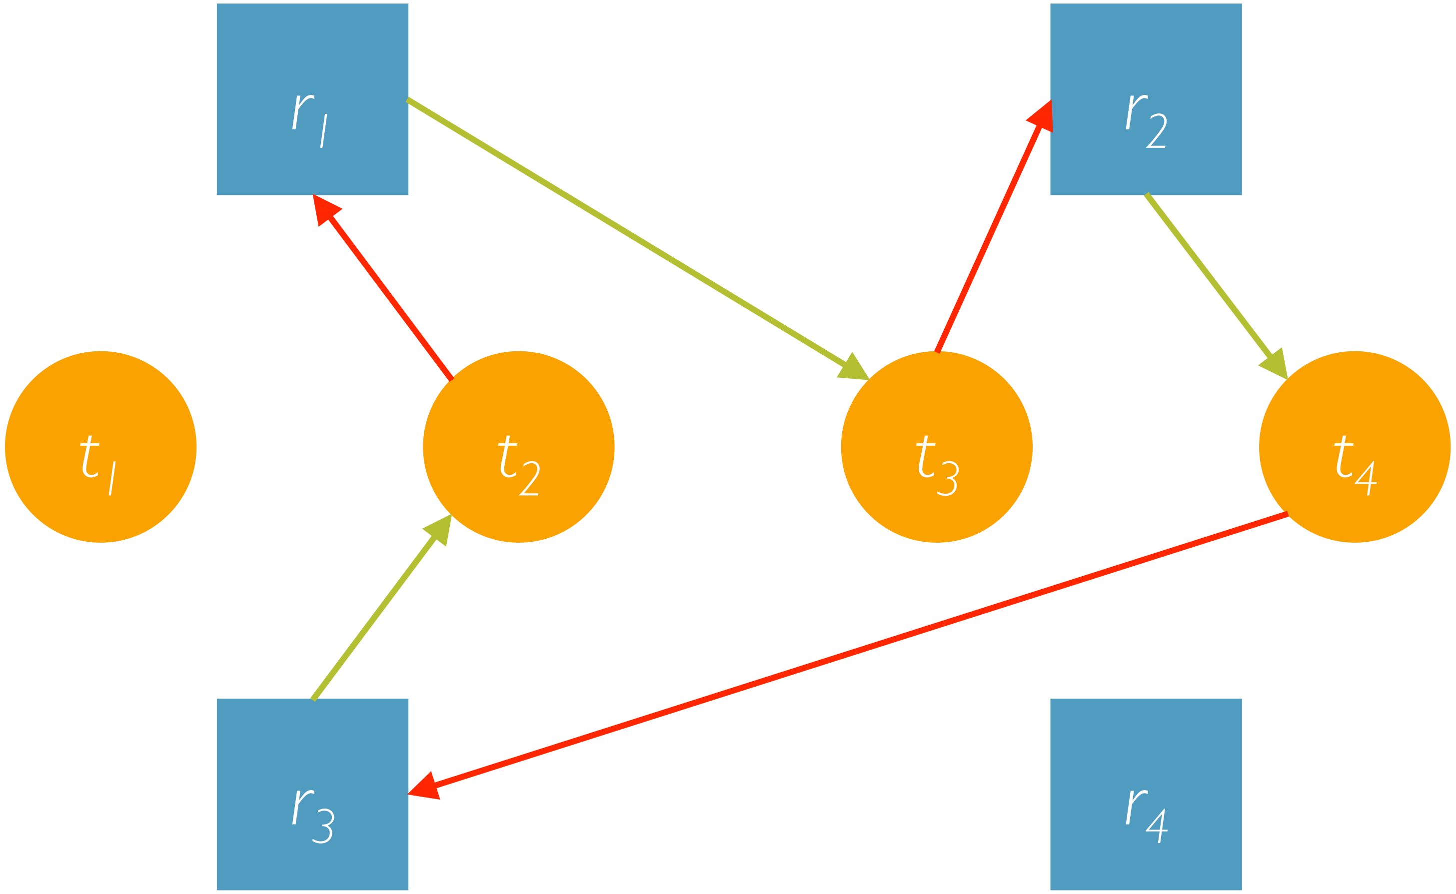


Deadlock Detection: Resource Allocation Graph



If the graph has no cycles, no deadlock **will ever** exist

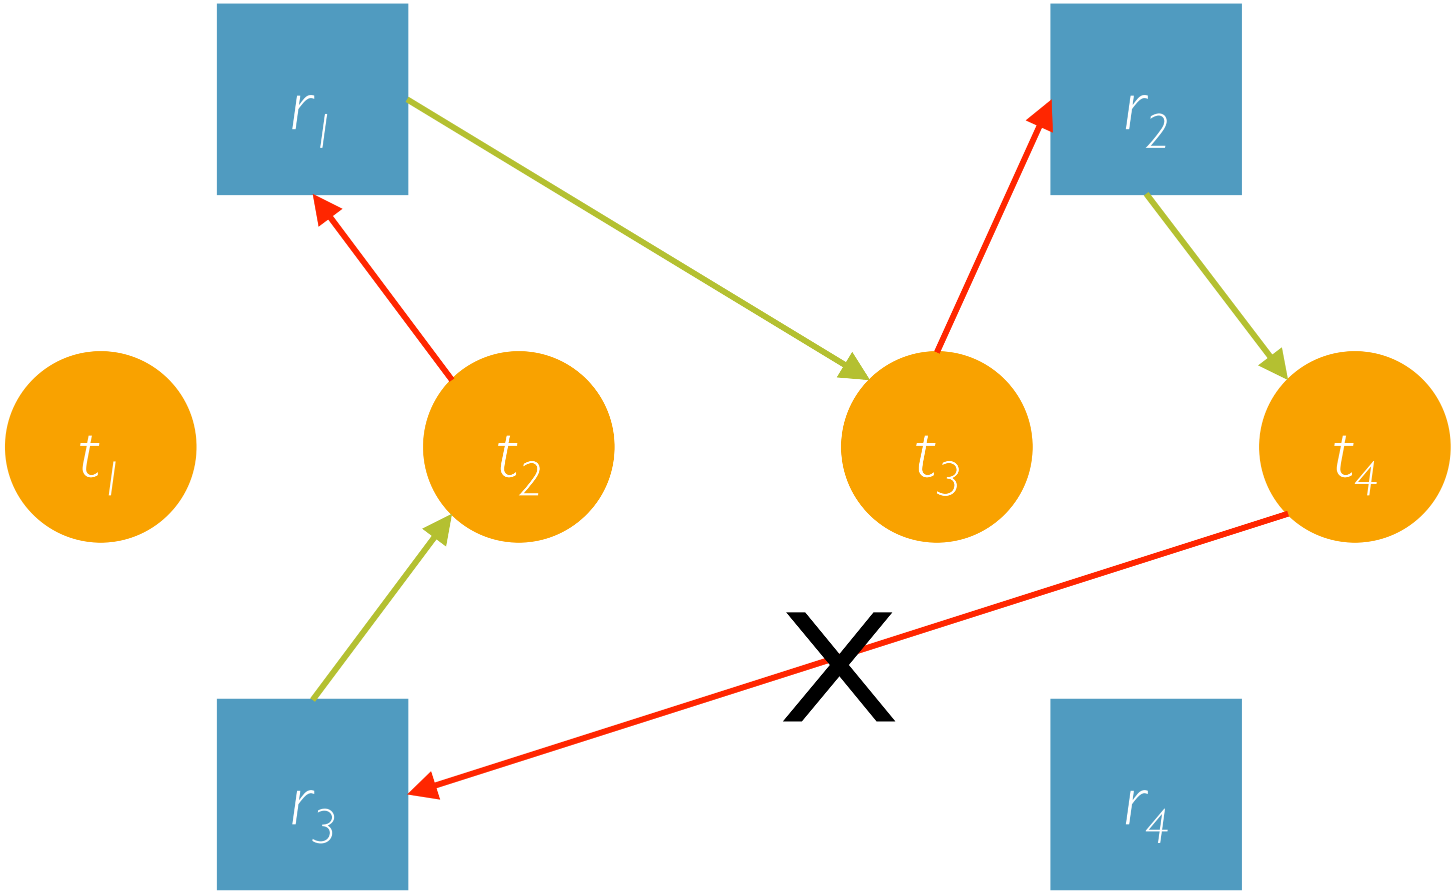
Deadlock Detection: Resource Allocation Graph



If the graph has no cycles, no deadlock **will ever** exist

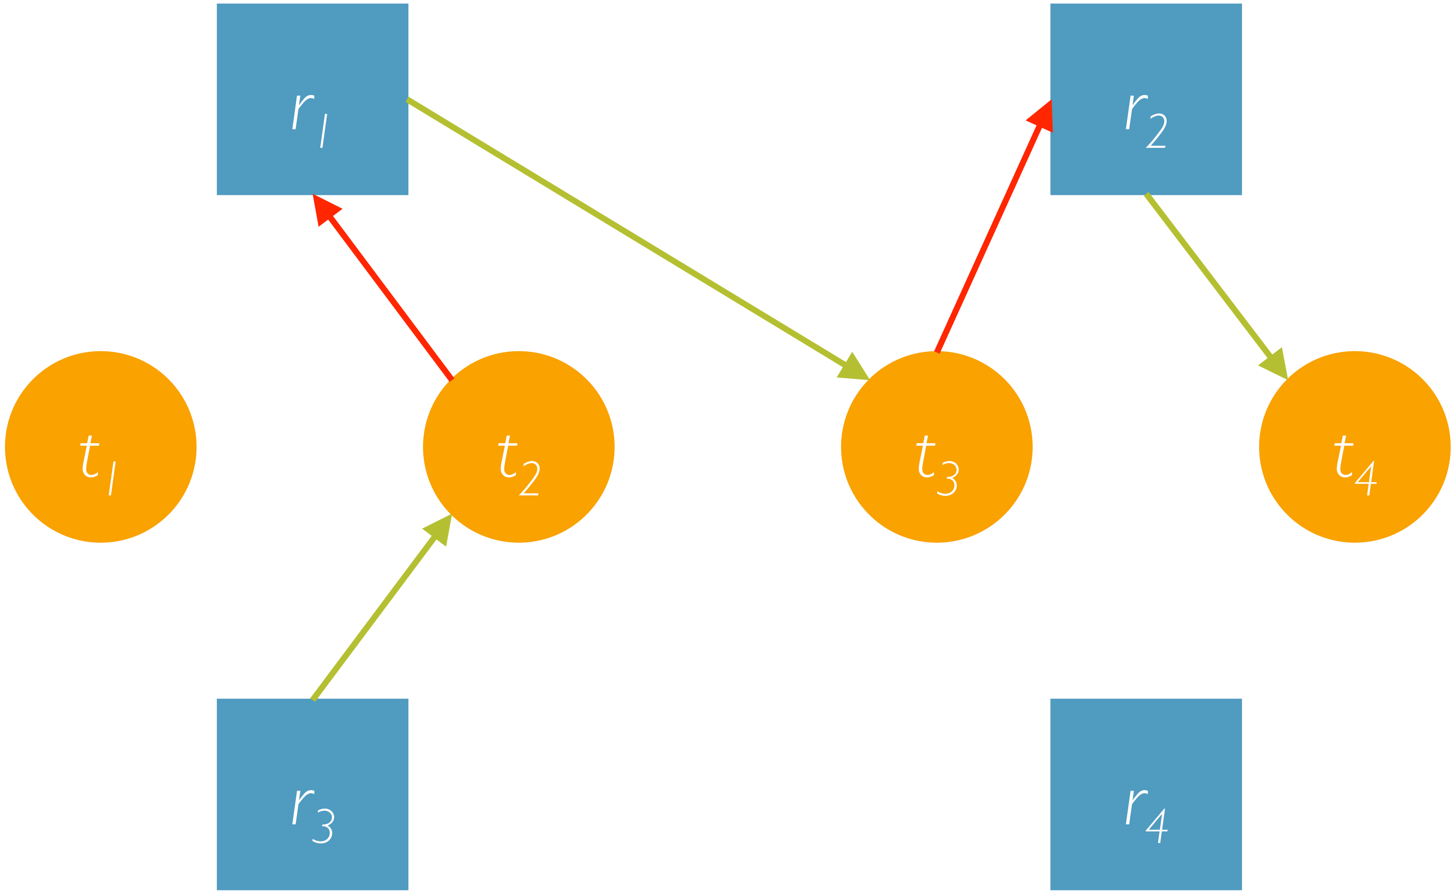
Why?

Deadlock Detection: Resource Allocation Graph



Suppose we remove the edge (t_4, r_3) so as to remove the cycle

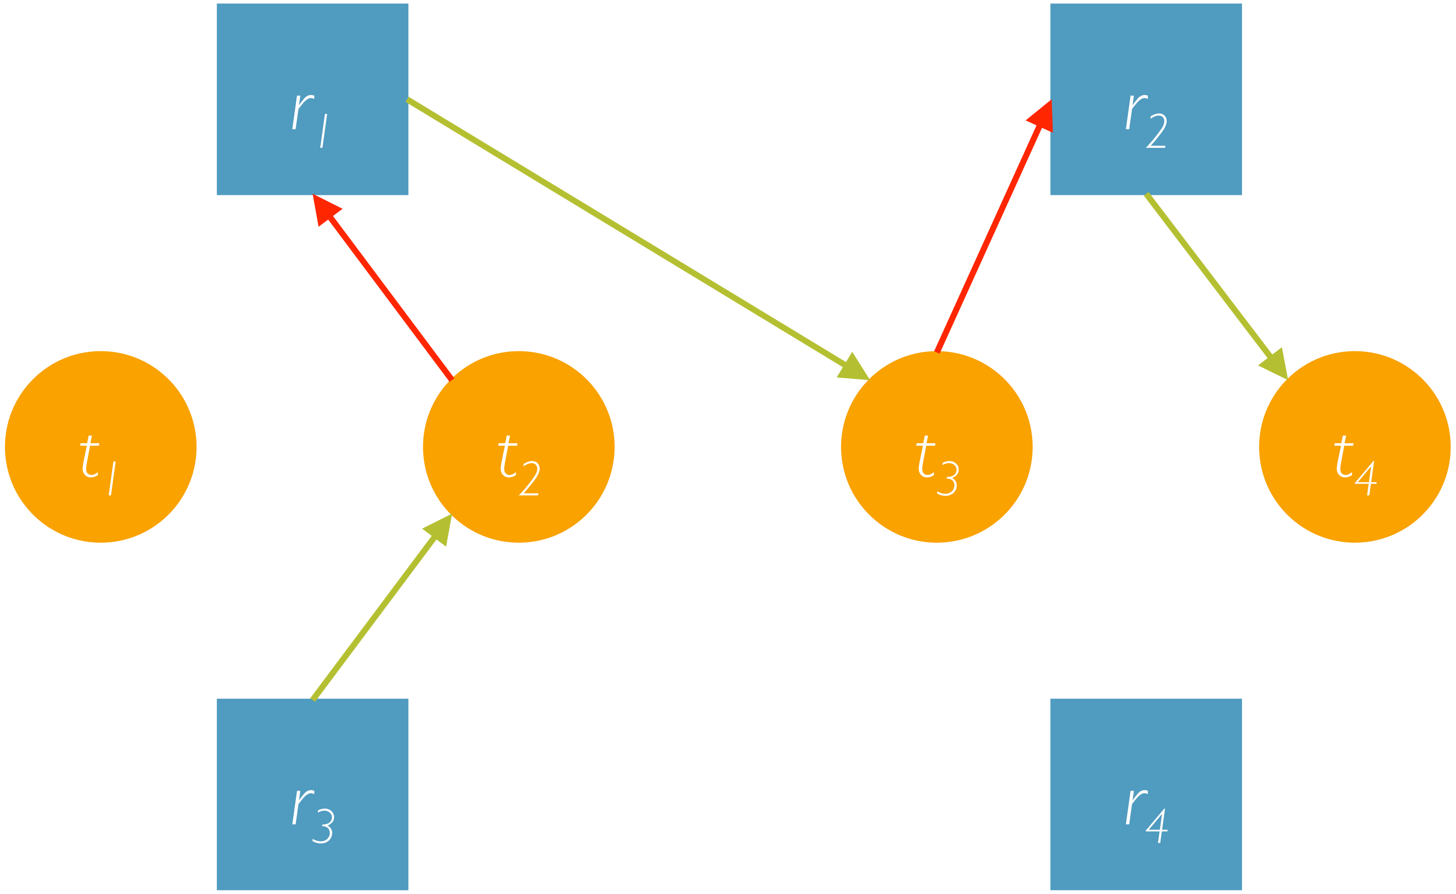
Deadlock Detection: Resource Allocation Graph



Suppose we remove the edge (t_4, r_3) so as to remove the cycle

No deadlock can occur as t_4 is not waiting on anything…

Deadlock Detection: Resource Allocation Graph

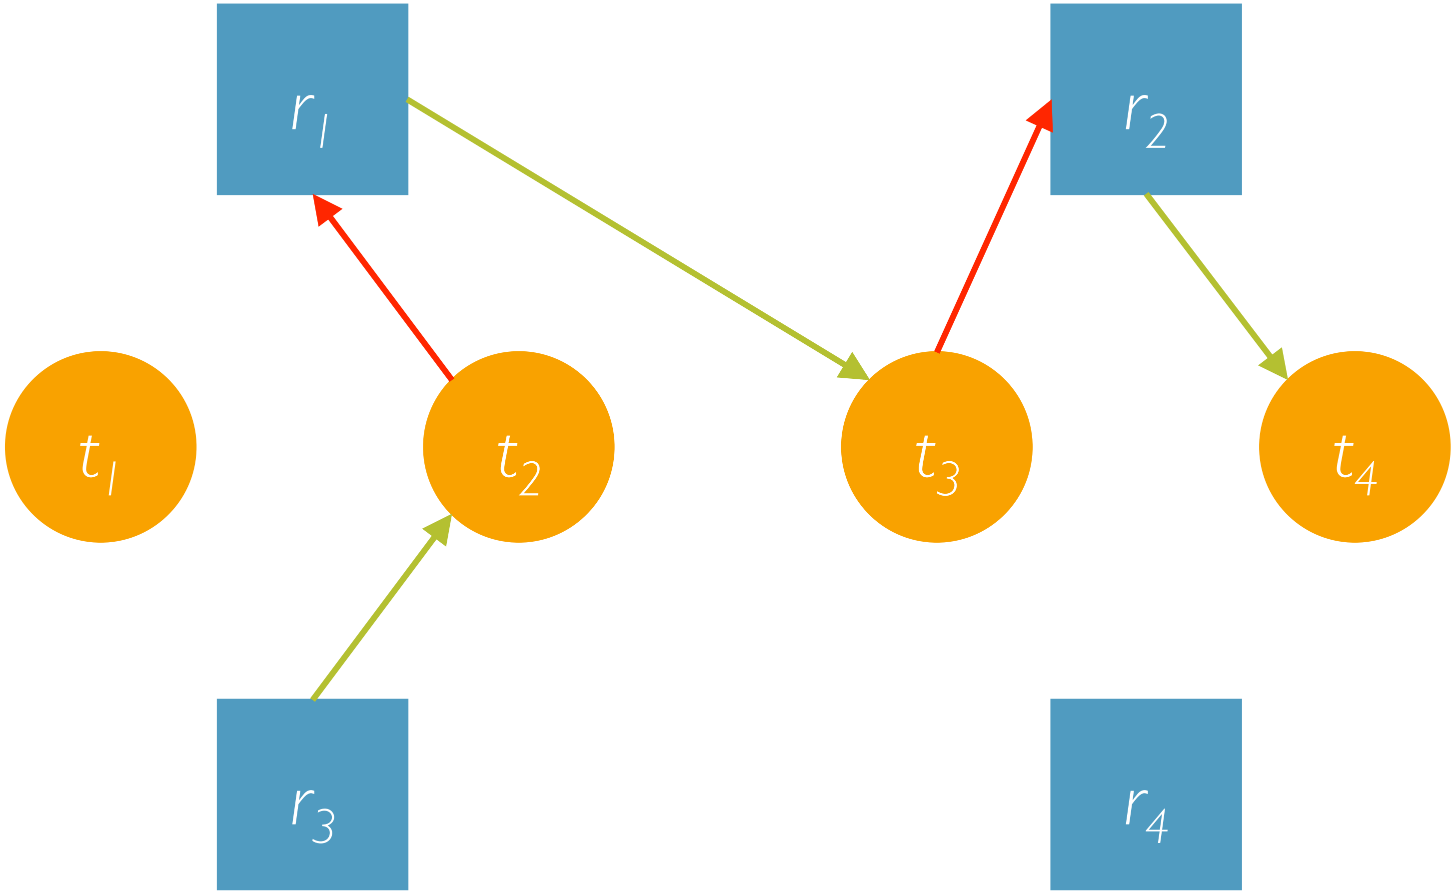


Suppose we remove the edge (t_4, r_3) so as to remove the cycle

No deadlock can occur as t_4 is not waiting on anything…

Therefore, t_4 can run and eventually will release r_2, which wakes up t_3

Deadlock Detection: Resource Allocation Graph



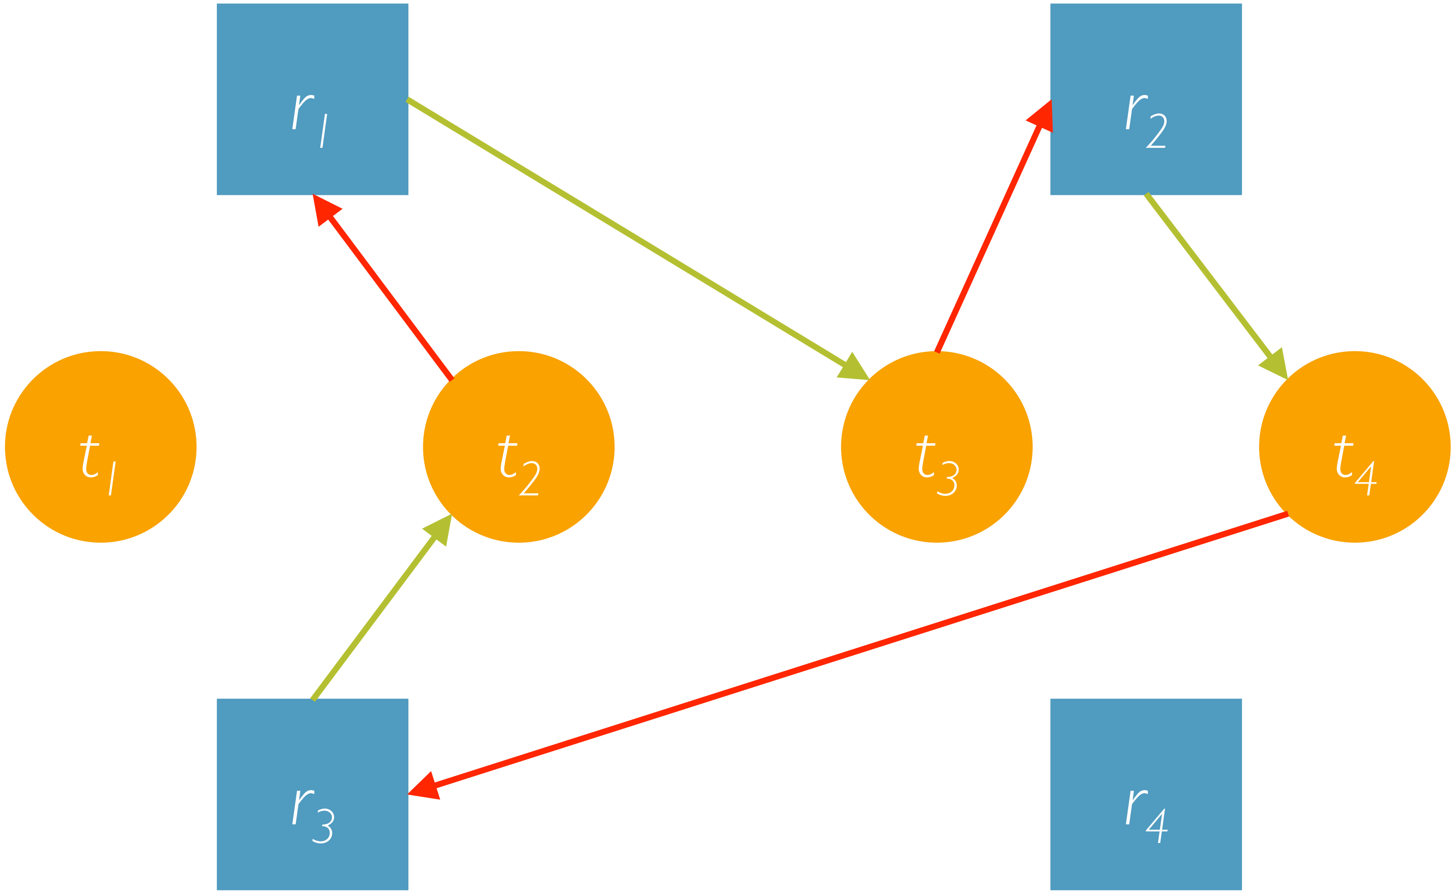
Suppose we remove the edge (t_4, r_3) so as to remove the cycle

No deadlock can occur as t_4 is not waiting on anything…

Therefore, t_4 can run and eventually will release r_2, which wakes up t_3

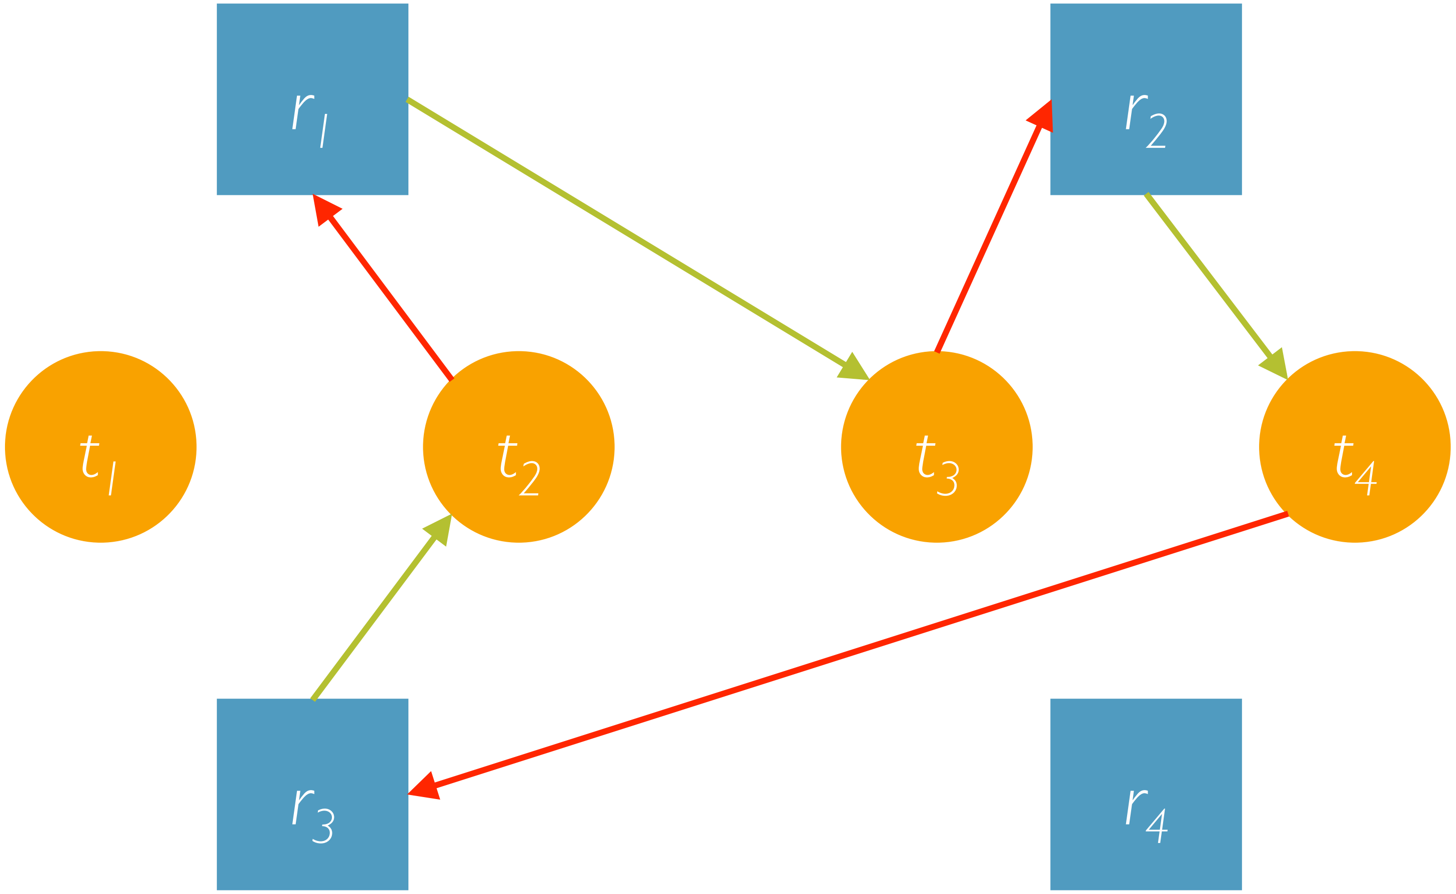
And so on and so forth…

Deadlock Detection: Resource Allocation Graph



If the graph has cycles, deadlock **might** exist

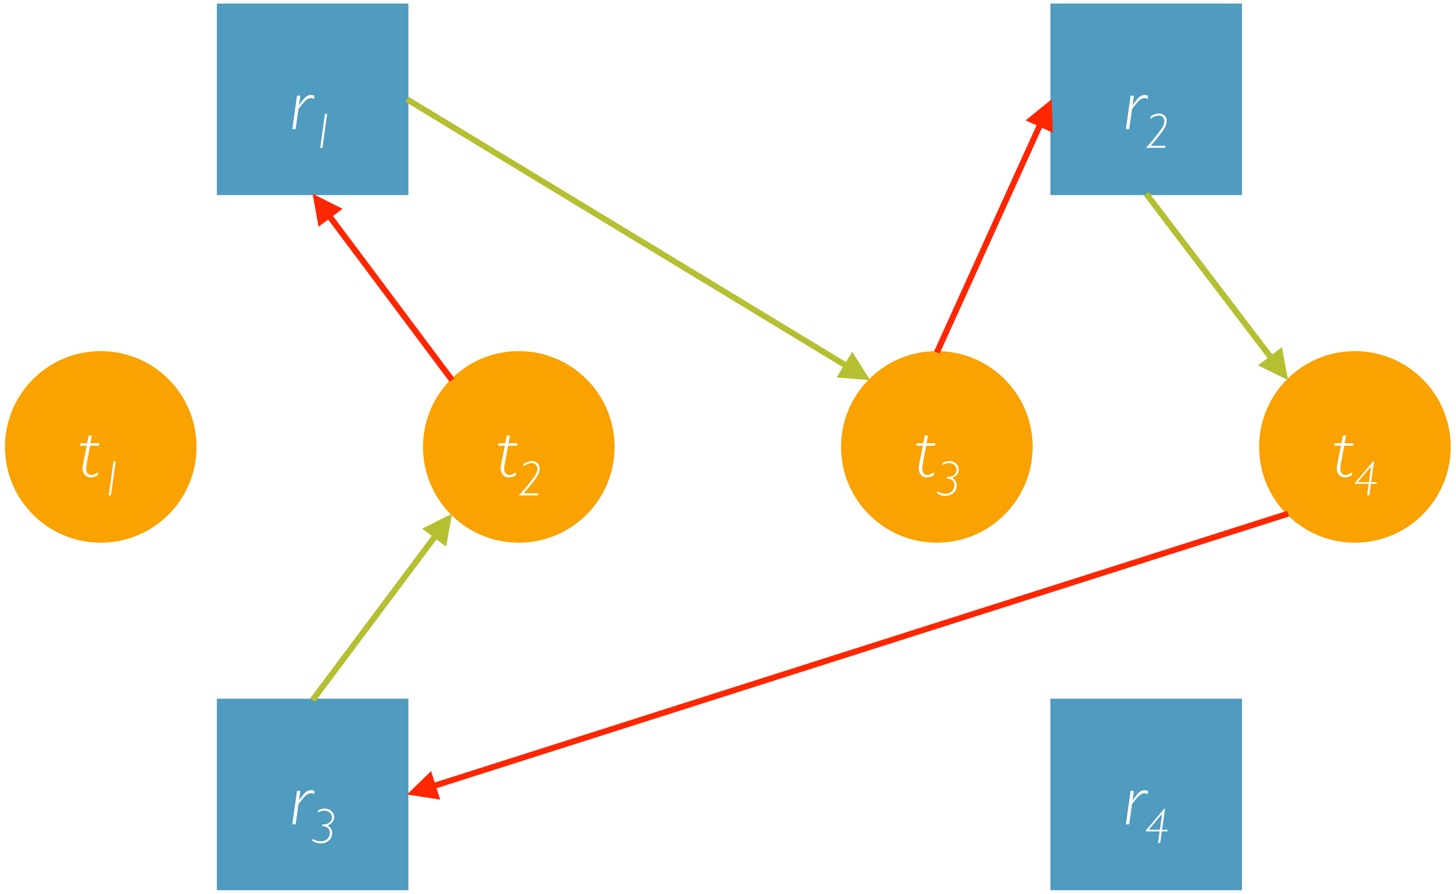
Deadlock Detection: Resource Allocation Graph



If the graph has cycles, deadlock **might** exist

Why?

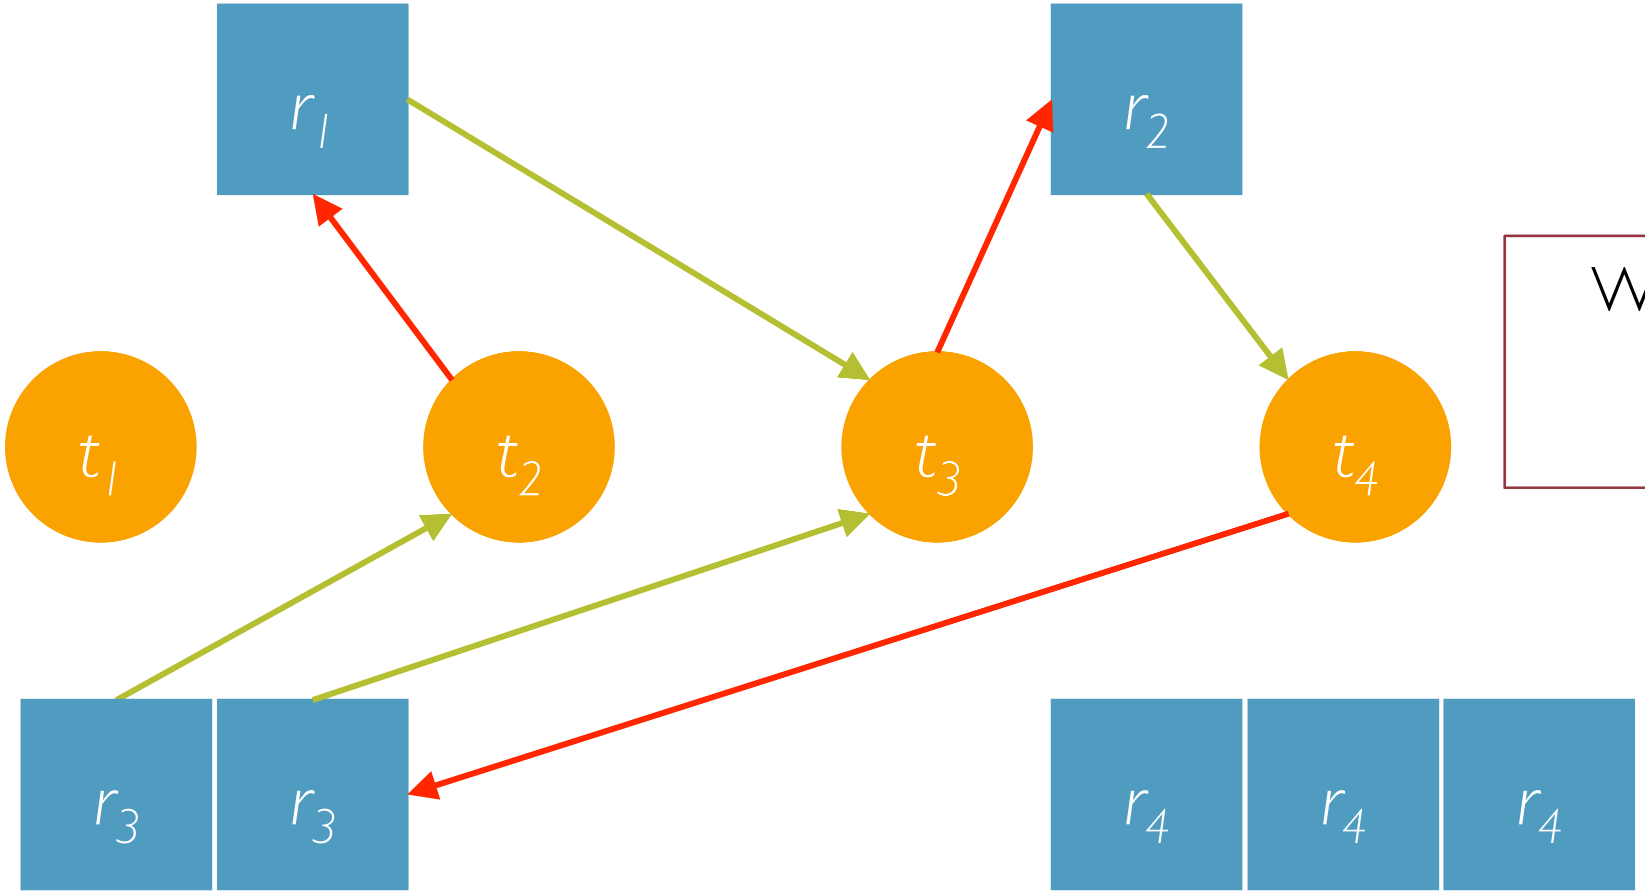
Deadlock Detection: Resource Allocation Graph



If the graph has cycles, deadlock **might** exist

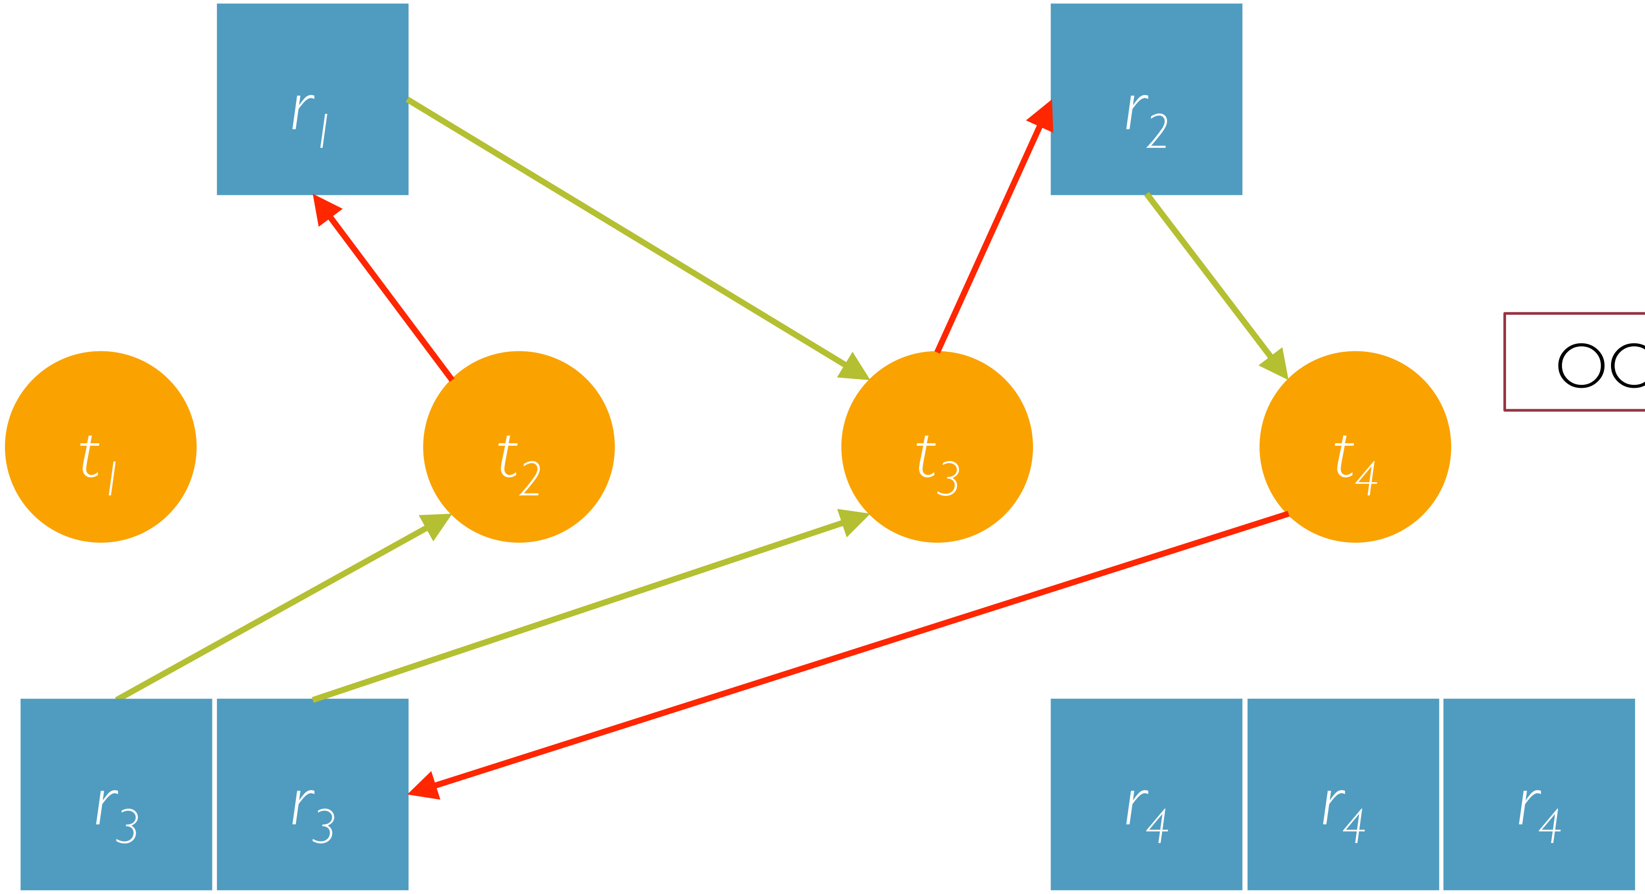
We are implicitly assuming the **multiplicity** of each resource is 1 (i.e., we have <u>one</u> r_1, <u>one</u> r_2, etc.)

Deadlock Detection: Resource Allocation Graph



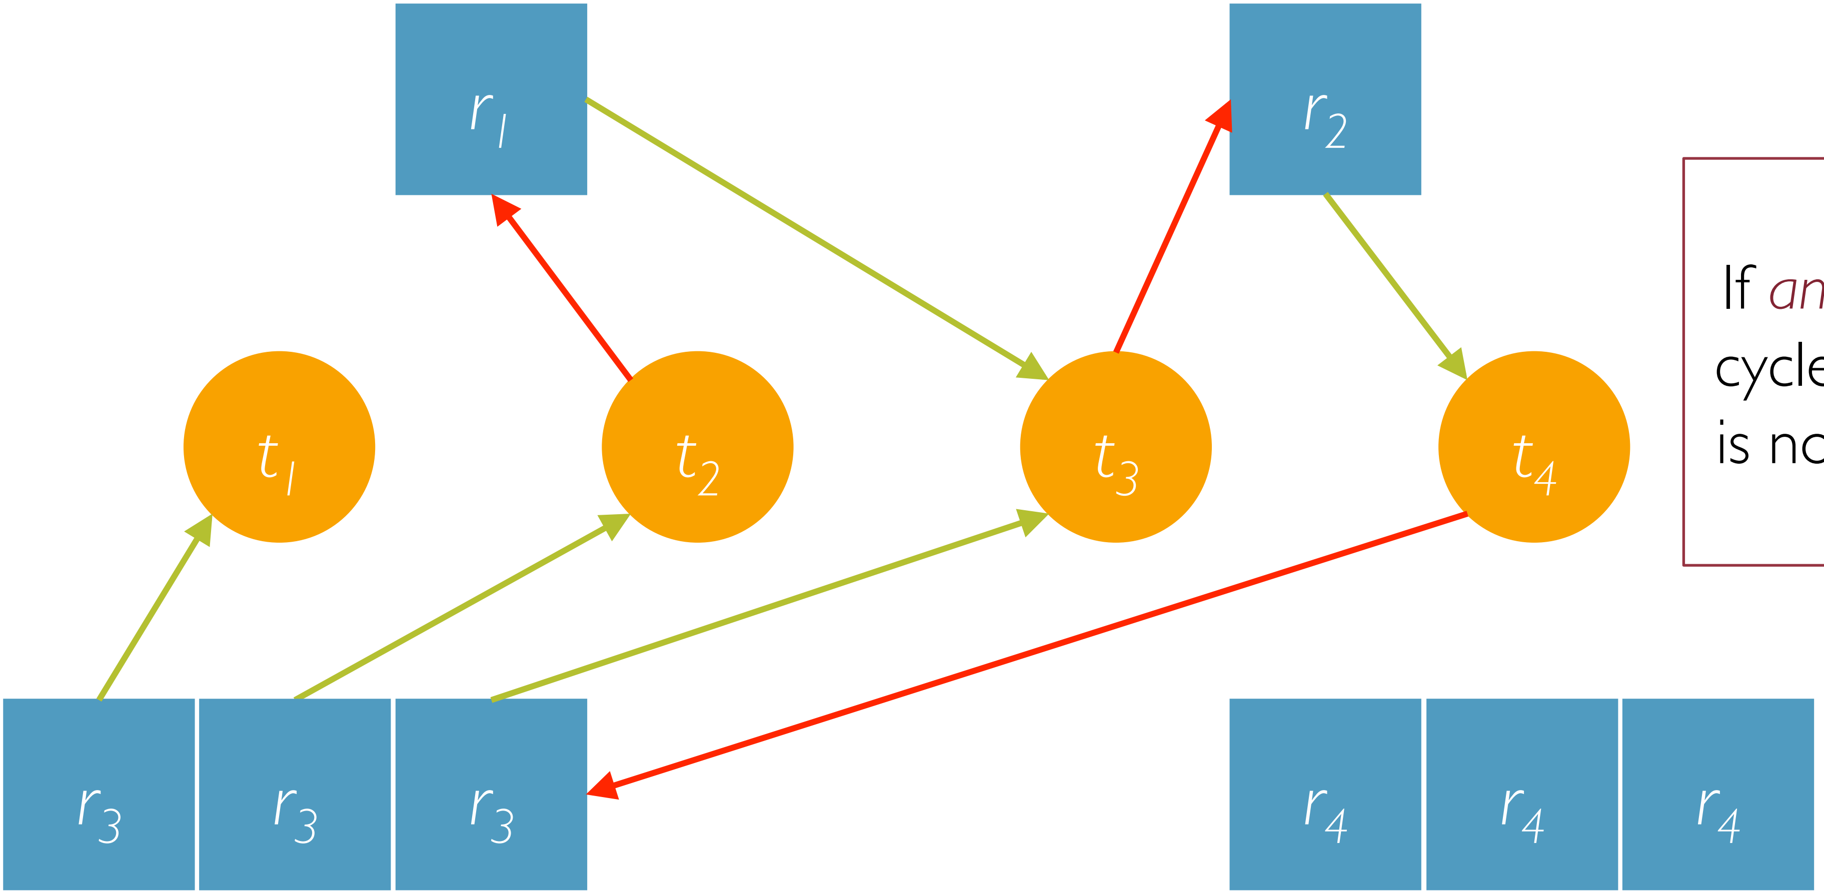
What if there are **multiple** instances of the same resource?

Deadlock Detection: Resource Allocation Graph



OOPS! This is still a deadlock

Deadlock Detection: Resource Allocation Graph



This works!
If *any* resource involved in the cycle is held by a thread which is not in the cycle (t_1) then we can make progress

Deadlock: Detect and Correct It!

- Scan the Resource Allocation Graph (RAG) for cycles, and then break those!

Deadlock: Detect and Correct It!

- Scan the Resource Allocation Graph (RAG) for cycles, and then break those!
- How? Several ways of doing it:
  - Kill all the threads in the cycle (quite harsh, ugh?)
  - Kill all the threads one at a time, forcing each one of them to release resource(s)
  - Preempt resources one at a time rolling back to a consistent status (e.g., common in database transactions)

Deadlock: Detect and Correct It!

- Scan the Resource Allocation Graph (RAG) for cycles, and then break those!
- How? Several ways of doing it:
  - Kill all the threads in the cycle (quite harsh, ugh?)
  - Kill all the threads one at a time, forcing each one of them to release resource(s)
  - Preempt resources one at a time rolling back to a consistent status (e.g., common in database transactions)
- We would like to be more precise than that…

Deadlock: Detect and Correct It!

- Detecting cycles on a directed graph $G=(V, E)$ is a quite costly operation

Deadlock: Detect and Correct It!

- Detecting cycles on a directed graph $G=(V, E)$ is a quite costly operation
- Known algorithms based on **depth-first search** (**DFS**) take $O(|V|+|E|)$ time
  → $O(|V|^2)$ as $|E| = O(|V|^2)$, and $|V|$ = #threads + #resources

Deadlock: Detect and Correct It!

- Detecting cycles on a directed graph $G=(V, E)$ is a quite costly operation
- Known algorithms based on **depth-first search** (**DFS**) take $O(|V|+|E|)$ time
  → $O(|V|^2)$ as $|E| = O(|V|^2)$, and $|V|$ = #threads + #resources
- When to run such a detection algorithm?
  - Before granting a resource → each granted request will take $O(|V|^2)$
  - When a request cannot be fulfilled → each failed request will take $O(|V|^2)$
  - On a regular schedule or when the CPU is under-utilized

Deadlock: Detect and Correct It!

- Detecting cycles on a directed graph $G=(V, E)$ is a quite costly operation
- Known algorithms based on **depth-first search** (**DFS**) take $O(|V|+|E|)$ time
  → $O(|V|^2)$ as $|E| = O(|V|^2)$, and $|V|$ = #threads + #resources
- When to run such a detection algorithm?
  - Before granting a resource → each granted request will take $O(|V|^2)$
  - When a request cannot be fulfilled → each failed request will take $O(|V|^2)$
  - On a regular schedule or when the CPU is under-utilized
- What do modern OSs do? Nothing! They leave it to the programmer!

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

Deadlock Prevention

- Ensure that *at least one* of the 4 necessary conditions doesn't hold

Deadlock Prevention

- Ensure that *at least one* of the 4 necessary conditions doesn't hold
  - Mutual Exclusion → make resources sharable (though not all can be shared)

Deadlock Prevention

- Ensure that *at least one* of the 4 necessary conditions doesn't hold
  - Mutual Exclusion → make resources sharable (though not all can be shared)
  - Hold and Wait → a thread cannot hold one resource when it requests another (enforce requests to be made all at once)

Deadlock Prevention

- Ensure that *at least one* of the 4 necessary conditions doesn't hold
  - Mutual Exclusion → make resources sharable (though not all can be shared)
  - Hold and Wait → a thread cannot hold one resource when it requests another (enforce requests to be made all at once)
  - No Preemption → if a thread requests a resource that cannot be allocated to it, the OS preempts (releases) all the resources that the thread is already holding
    - <u>Problem:</u> not all resources can be easily preempted (e.g., printers)

Deadlock Prevention

- Ensure that *at least one* of the 4 necessary conditions doesn't hold
  - Mutual Exclusion → make resources sharable (though not all can be shared)
  - Hold and Wait → a thread cannot hold one resource when it requests another (enforce requests to be made all at once)
  - No Preemption → if a thread requests a resource that cannot be allocated to it, the OS preempts (releases) all the resources that the thread is already holding
    - <u>Problem:</u> not all resources can be easily preempted (e.g., printers)
  - Circular Wait → impose an ordering (i.e., numbering) on resources and enforce to request them in such order

Our Journey

- What is deadlock?
- Conditions for deadlock to happen
- Deadlock detection
- Deadlock prevention
- Deadlock avoidance

Deadlock Avoidance: Resource Reservation

Each thread provides information about the maximum number of resources it might need during execution

$$
\begin{aligned}
m_i &= \textit{maximum} \text{ number of resources that thread } i \textit{ might} \text{ request} \\
c_i &= \textit{current} \text{ number of resources that thread } i \text{ is holding} \\
C &= \sum_{i=1}^{n} c_i = \textit{total} \text{ number of resources currently allocated} \\
R &= \textit{maximum} \text{ number of resources overall available}
\end{aligned}
$$

Any thread sequence is safe if for each thread it holds that:

$$
\underbrace{m_i - c_i}_{\text{resources } t_i \text{ might still request}} \leq \underbrace{R - C}_{\text{resources currently available}} + \underbrace{\sum_{j=1}^{i-1} c_j}_{\text{resources currently allocated up to } t_j, j<i}
$$

Deadlock Avoidance: Safe State

- A state in which there is a safe sequence for the threads
- An unsafe state does not necessarily mean deadlock (i.e., some threads may not request the maximum number of resources as declared)
- Grant a resource to a thread if the new state is safe, otherwise make it wait even if the resource is available
- This policy ensures no circular-wait condition exists

Deadlock Avoidance: Example

- 3 threads: t_1, t_2, and t_3 are competing for 12 tape drives (resources)
- Currently, 11 drives are allocated to the threads, leaving 1 available

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	4	8

$\boxed{\text{Is the current state safe?}}$

Deadlock Avoidance: Example

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	4	8

The current state is safe in that there exists a sequence of threads (t_1, t_2, t_3) where each one will get the maximum number of resources without waiting

Deadlock Avoidance: Example

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	4	8

The current state is safe in that there exists a sequence of threads (t_1, t_2, t_3) where each one will get the maximum number of resources without waiting

t_1 can complete using the current allocation and the 1 drive left

Deadlock Avoidance: Example

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	4	8

The current state is safe in that there exists a sequence of threads (t_1, t_2, t_3) where each one will get the maximum number of resources without waiting

t_1 can complete using the current allocation and the 1 drive left

t_2 can use the current allocation, plus t_1's resources and 1 drive left (4 drives)

Deadlock Avoidance: Example

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	4	8

The current state is safe in that there exists a sequence of threads (t_1, t_2, t_3) where each one will get the maximum number of resources without waiting

t_1 can complete using the current allocation and the **1 drive** left

t_2 can use the current allocation, plus t_1's resources and 1 drive left (**4 drives**)

t_3 can use the current allocation, plus t_1's & t_2's resources and 1 drive left (**8 drives**)

Deadlock Avoidance: Example

Thread	m_i	c_i	$m_i - c_i$
t_1	4	3	1
t_2	8	4	4
t_3	12	5	7

Suppose t_3 requests one more drive, then now there are no more available drives

Theoretically, everything might still work (e.g., t_1 may never request another drive)

However, t_3 must wait because allocating that extra drive would lead to an unsafe state, which in turn might lead to deadlock

Deadlock Avoidance: Resource Allocation Graph

- An extension of the original definition of resource allocation graph

Deadlock Avoidance: Resource Allocation Graph

- An extension of the original definition of resource allocation graph
- Edges can now be of 3 types:
  - Request Edge → a directed edge (t_i, r_j) indicates that t_i has requested r_j, but not yet acquired
  - Claim (dotted) Edge → a directed edge (t_i, r_j) indicates that t_i might request r_j in the future
  - Assignment Edge → a directed edge (r_j, t_i) indicates that the OS has allocated r_j to t_i

Deadlock Avoidance: Resource Allocation Graph

- An extension of the original definition of resource allocation graph
- Edges can now be of 3 types:
  - Request Edge → a directed edge (t_i, r_j) indicates that t_i has requested r_j, but not yet acquired
  - Claim (dotted) Edge → a directed edge (t_i, r_j) indicates that t_i might request r_j in the future
  - Assignment Edge → a directed edge (r_j, t_i) indicates that the OS has allocated r_j to t_i
- Satisfying a request means converting a claim into an assignment edge

Deadlock Avoidance: Resource Allocation Graph

- A cycle in this extended RAG indicates an unsafe state

Deadlock Avoidance: Resource Allocation Graph

- A cycle in this extended RAG indicates an unsafe state
- If the allocation results in an unsafe state, this will be denied even if the resource is actually available

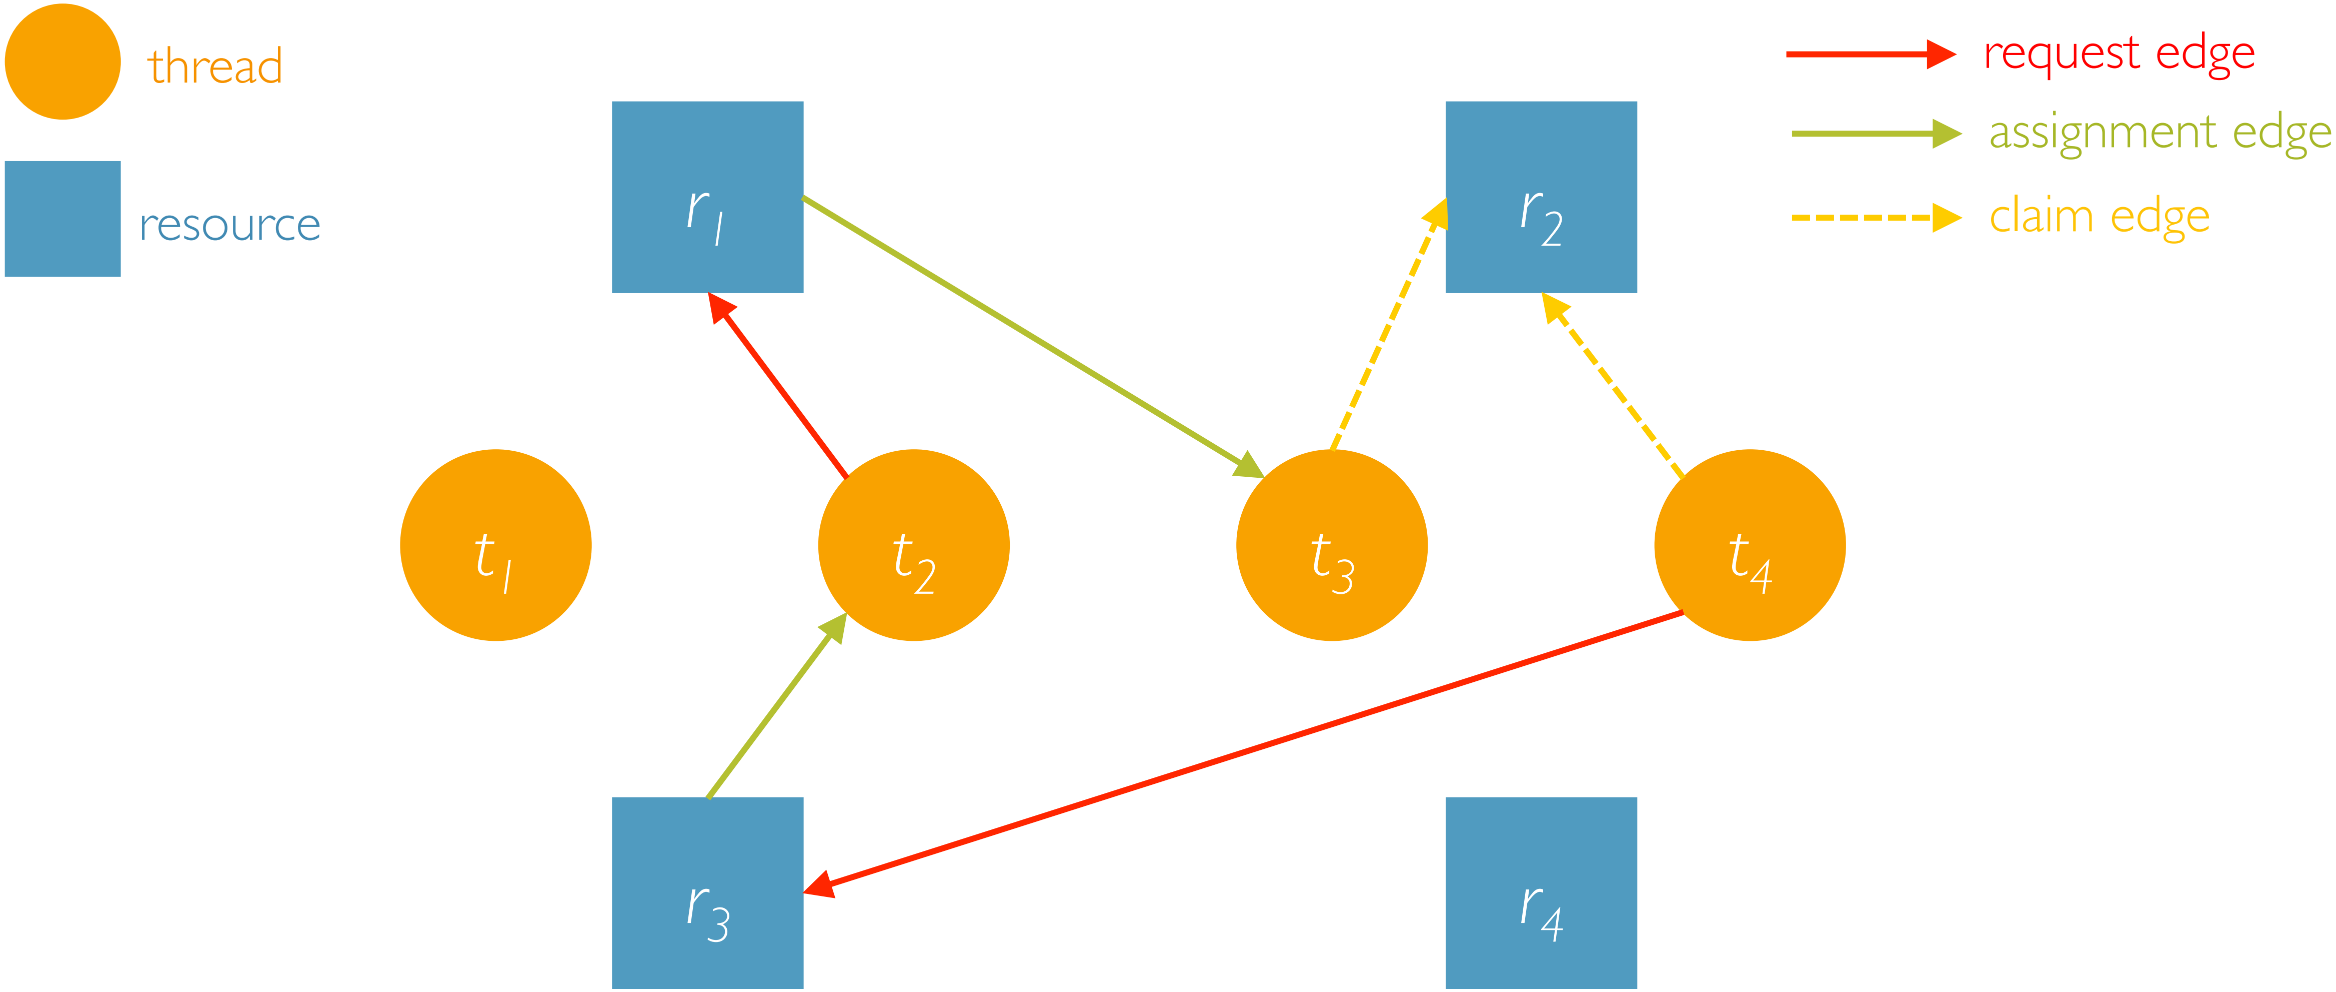
Deadlock Avoidance: Resource Allocation Graph

- A cycle in this extended RAG indicates an unsafe state
- If the allocation results in an unsafe state, this will be denied even if the resource is actually available
- In other words, the claim edge is converted into a request edge and the thread will wait

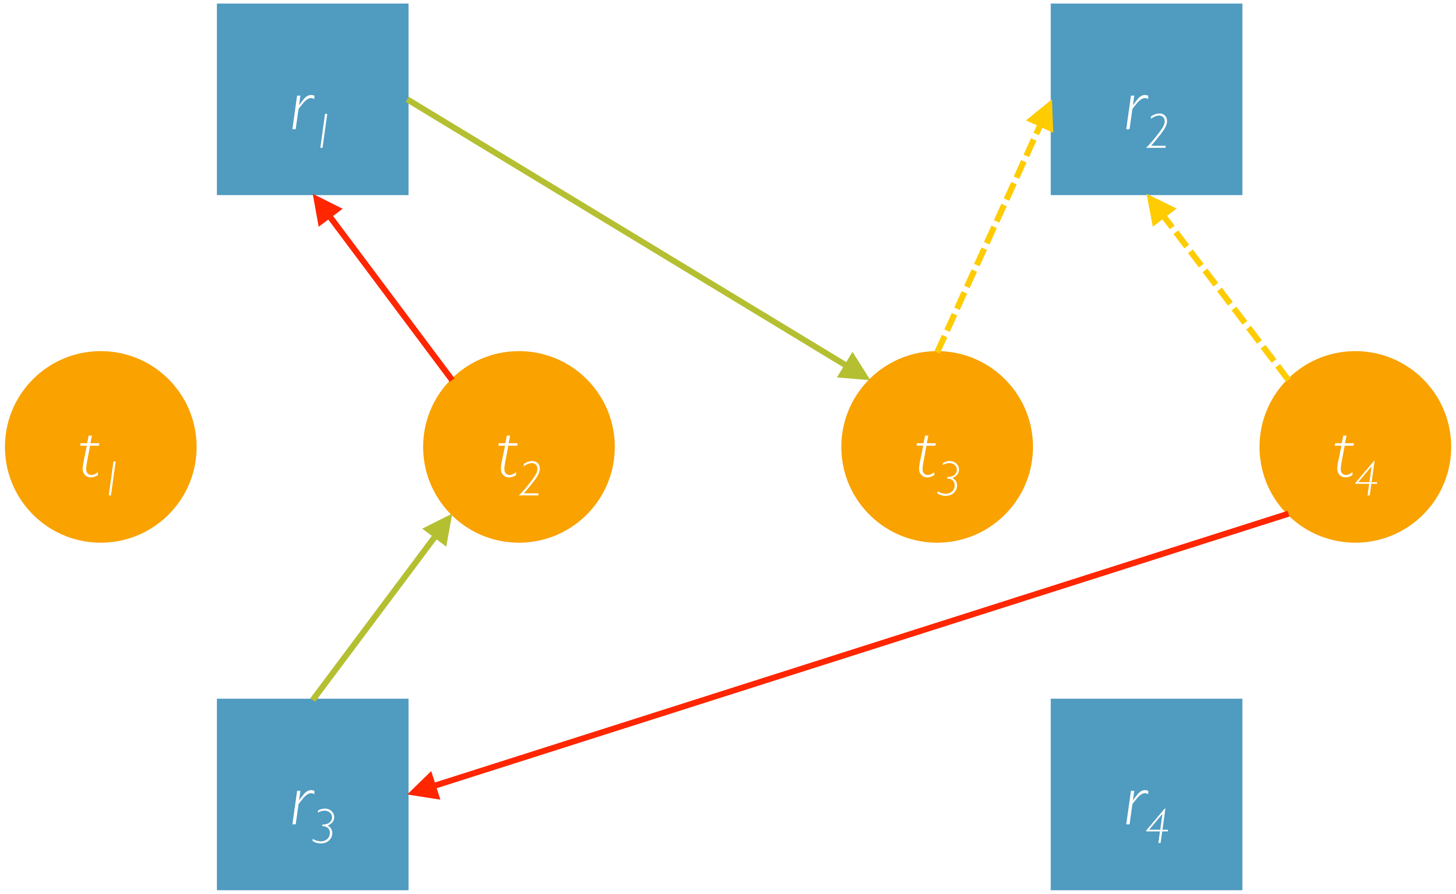
Deadlock Avoidance: Resource Allocation Graph

- A cycle in this extended RAG indicates an unsafe state
- If the allocation results in an unsafe state, this will be denied even if the resource is actually available
- In other words, the claim edge is converted into a request edge and the thread will wait
- NOTE: This solution does not work when there are multiple instances of the *same* resource

Deadlock Avoidance: Resource Allocation Graph

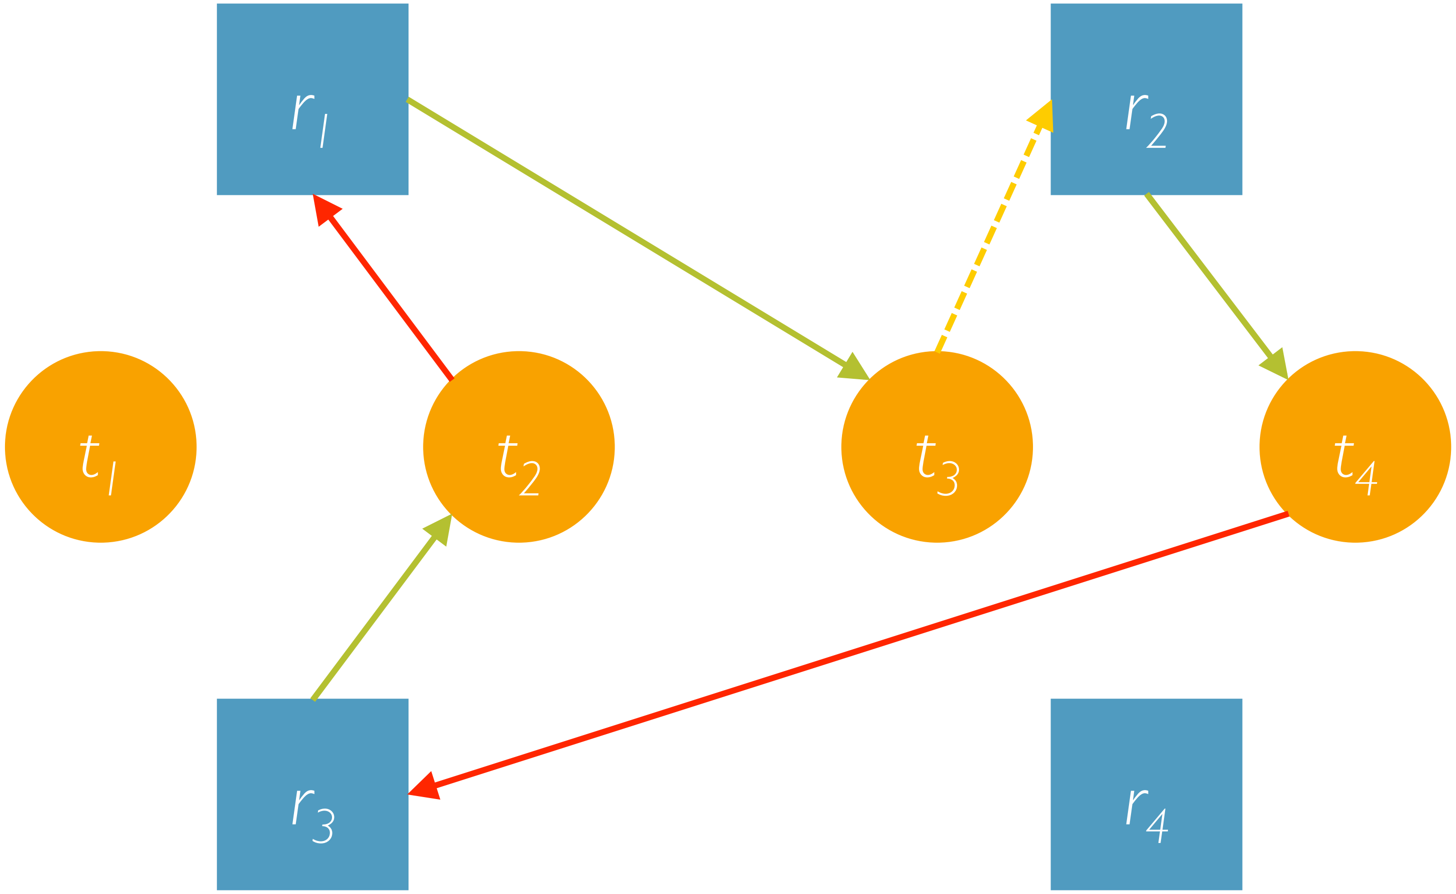


Deadlock Avoidance: Resource Allocation Graph



What happens if t_4 is given r_2?

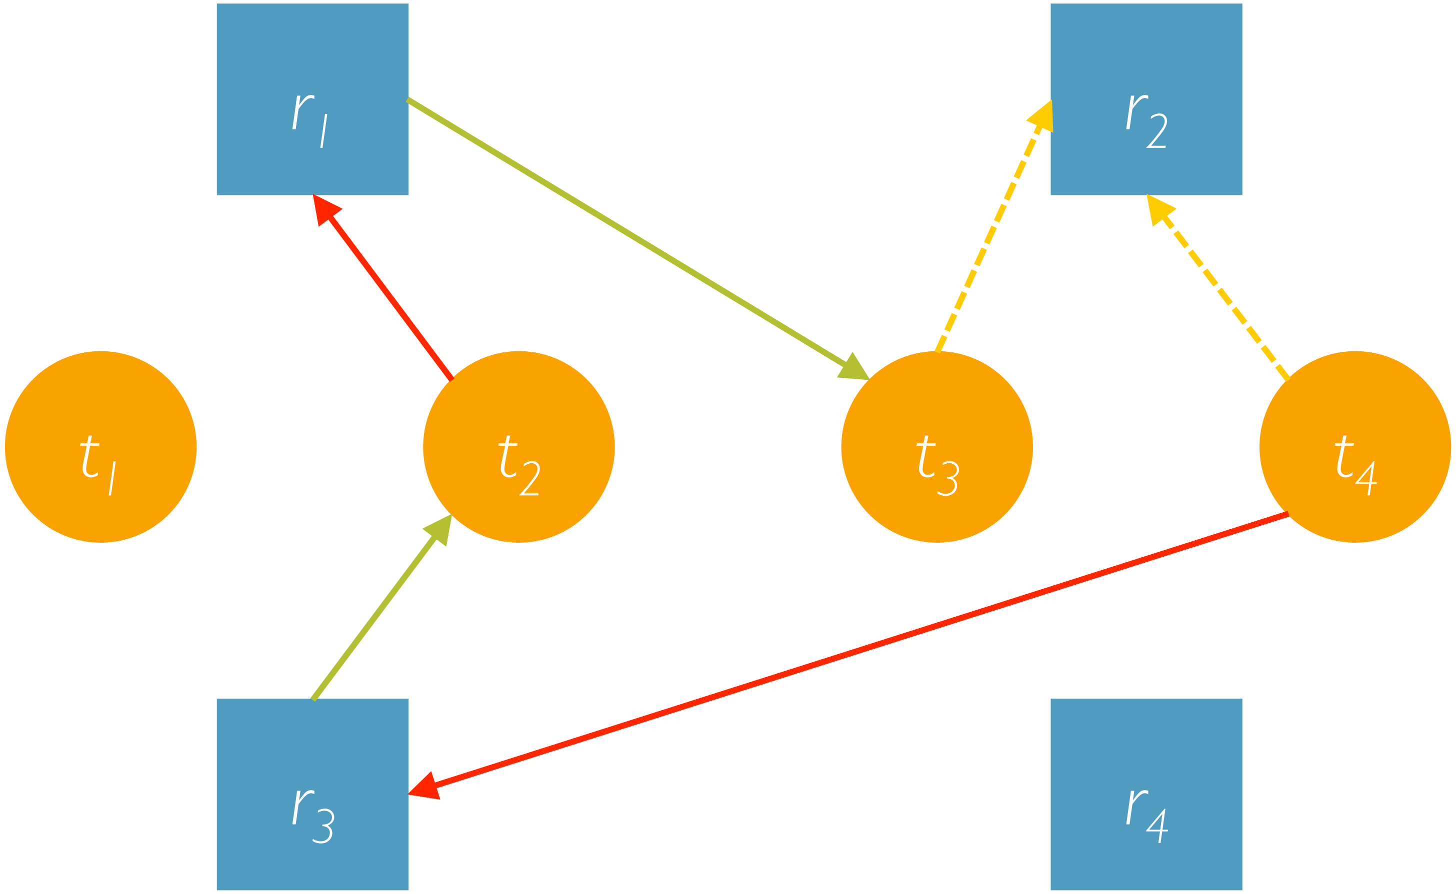
Deadlock Avoidance: Resource Allocation Graph



We are introducing a potential cycle (t_3 requests r_2), which in turn might cause deadlock

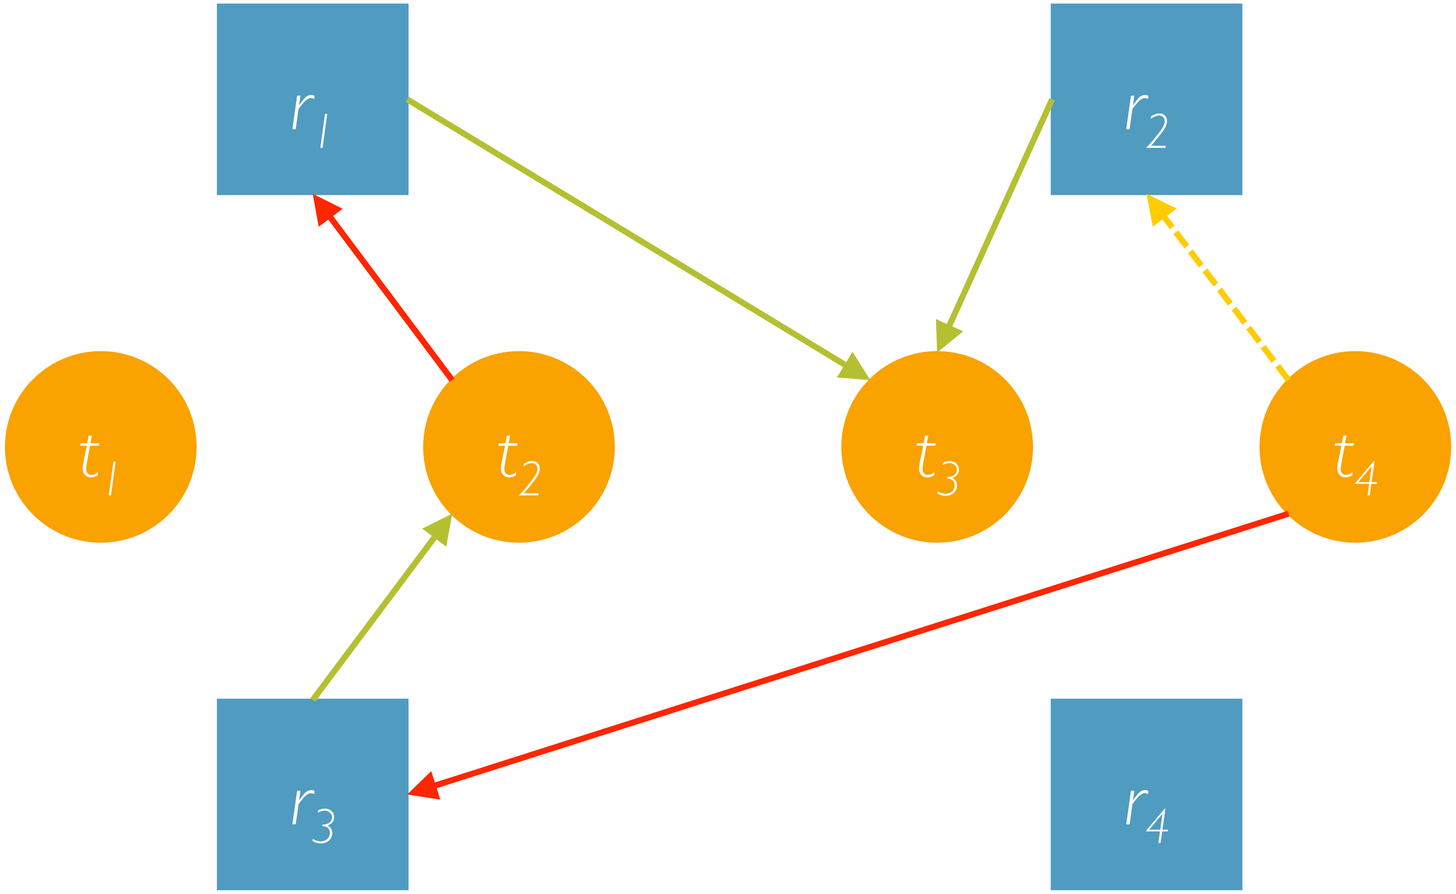
unsafe state

Deadlock Avoidance: Resource Allocation Graph



What happens if t_3 is given r_2?

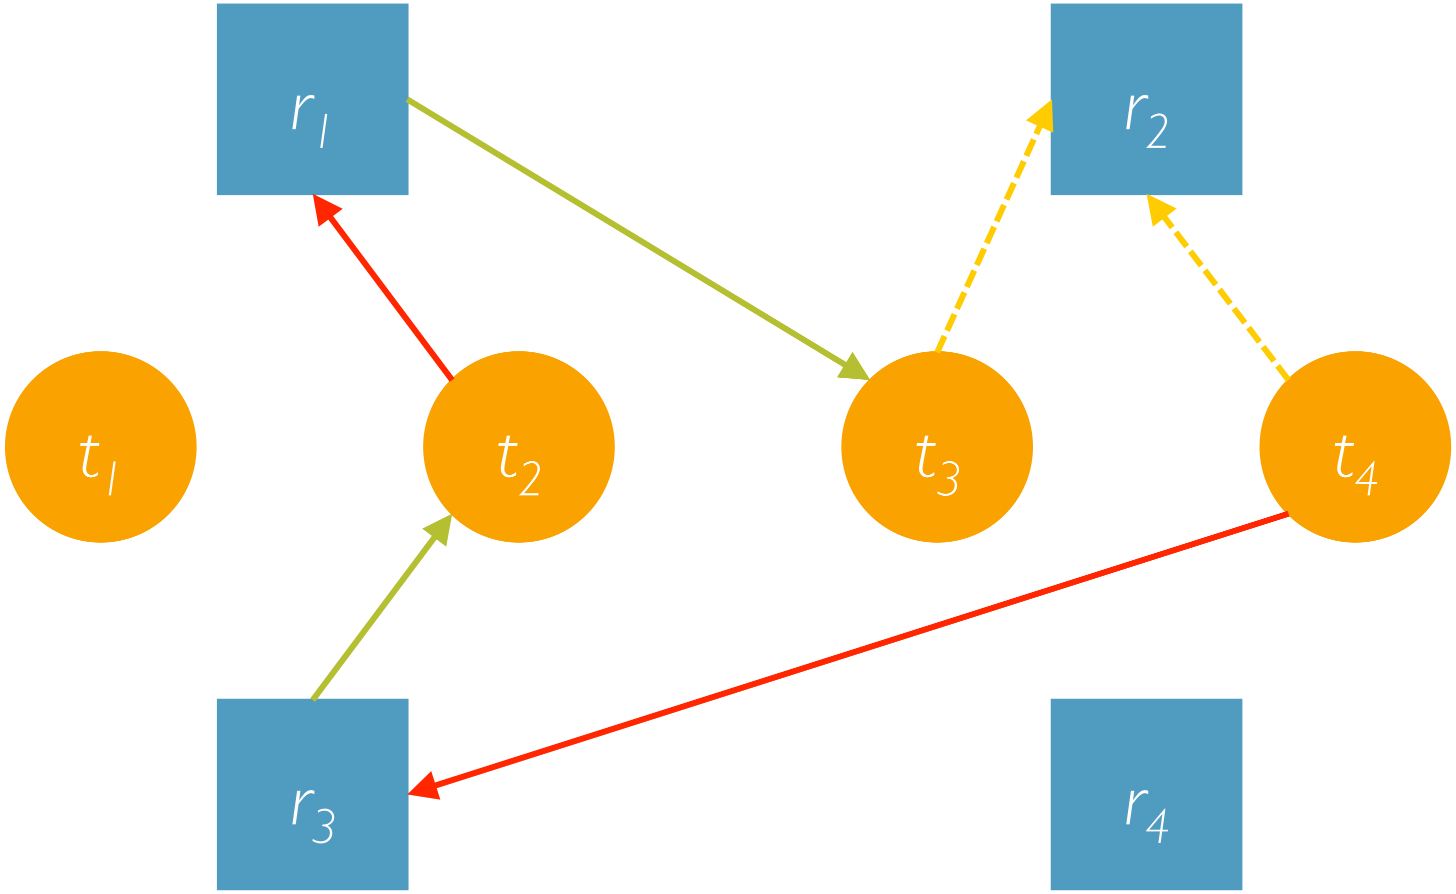
Deadlock Avoidance: Resource Allocation Graph



We are **not** introducing any potential cycle (t_4 requests r_2)

safe state

Deadlock Avoidance: Resource Allocation Graph



Start from a safe state

Invariant

Accept a request iff we move from a safe state to another

Banker's Algorithm

- Handles multiple instances of the same resource
- Forces threads to provide information on what resource they might need, in advance
- The resources requested must not exceed the total available in the system
- The algorithm allocates resources to a requesting thread if the allocation leaves the system in a safe state, otherwise the thread waits

Banker's Algorithm: Data Structures

- `n` = number of threads; `m` = number of resource types
- `available[1..m]`: `m`-dimensional vector
  - `available[j] = k` means there are `k` resources of type `j` available
- `max[1..n, 1..m]`: `n` × `m` matrix
  - `max[i, j] = k` means thread `i` may require at most `k` resources of type `j`
- `allocation[1..n, 1..m]`: `n` × `m` matrix
  - `allocation[i, j] = k` means thread `i` has allocated `k` resources of type `j`
- `need[1..n, 1..m]`: `n` × `m` matrix
  - `need[i, j] = max[i, j] - allocation[i, j] = k` means thread `i` may need `k` more resources of type `j` to complete its task

Banker's Algorithm: Idea

- The algorithm is divided in 2 tasks:
  - **`isSafeState`** → given the current status of allocation of resources, tests if this is a safe state
  - **`resourceRequest`** → given a thread and its resource request decides if such a request can be satisfied

Banker's Algorithm: Idea

- The algorithm is divided in 2 tasks:
  - **`isSafeState`** → given the current status of allocation of resources, tests if this is a safe state
  - **`resourceRequest`** → given a thread and its resource request decides if such a request can be satisfied
- A request can be satisfied iff this leads to a safe state!

Banker's Algorithm: Idea

- The algorithm is divided in 2 tasks:
  - **`isSafeState`** → given the current status of allocation of resources, tests if this is a safe state
  - **`resourceRequest`** → given a thread and its resource request decides if such a request can be satisfied
- A request can be satisfied iff this leads to a safe state!
- In other words, the second tasks uses the output of the first one in order to make a decision

Banker's Algorithm: `isSafeState`

1. Let `work` and `finish` be vectors of length `m` and `n`, respectively

   Initialize: `work = available; finish[i] = false;` for all `i`

2. Find an `i` such that:

   `finish[i] = false && need[i] ≤ work`

   If no such `i` exists, go to step 4.

3. Assume thread `i` executes:

   `work = work + allocation[i]; finish[i] = true;` go to step 2.

4. If `finish[i] == true` for all `i`, the system is in a safe state

Banker's Algorithm: `requestResource`

Input: `i` (thread) and `request` an `m`-dimensional vector of requests

1. If `request > need[i]` raise an error as thread `i` is attempting to request more resources that it claimed, otherwise go to step 2.
2. If `request > available` thread `i` must wait since resources are not available, otherwise go to step 3.
3. Even if resources are available, test if this allocation will lead to a safe state by simulating it

```
available -= request; allocation[i] += request; need[i] -= request;
isSafeState() ? OK : rollback() and wait()
```

Banker's Algorithm: Example

A snapshot of the current state of the system

		RESOURCES								
		MAX			ALLOCATION			AVAILABLE		
		A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1			
	T_1	1	7	5	1	0	0			
	T_2	2	3	5	1	3	5			
	T_3	0	6	5	0	6	3			
	Total				2	9	9	1	5	2

Banker's Algorithm: Example

Q1: How many resources of type A, B, and C are there *overall*?

		RESOURCES								
		MAX			ALLOCATION			AVAILABLE		
		A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1			
	T_1	1	7	5	1	0	0			
	T_2	2	3	5	1	3	5			
	T_3	0	6	5	0	6	3			
	Total				2	9	9	1	5	2

Banker's Algorithm: Example

Q1: How many resources of type A, B, and C are there *overall*?

		RESOURCES								
		MAX			ALLOCATION			AVAILABLE		
		A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1			
	T_1	1	7	5	1	0	0			
	T_2	2	3	5	1	3	5			
	T_3	0	6	5	0	6	3			
	Total				2	9	9	1	5	2

$A = 2 + 1 = 3$

$B = 9 + 5 = 14$

$C = 9 + 2 = 11$

Banker's Algorithm: Example

Q2: What is the content of the NEED matrix?

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1						
	T_1	1	7	5	1	0	0						
	T_2	2	3	5	1	3	5						
	T_3	0	6	5	0	6	3						
	Total				2	9	9	1	5	2			

Banker's Algorithm: Example

Q2: What is the content of the NEED matrix?

NEED[i, j] = MAX[i, j] – ALLOCATION[i, j]

		RESOURCES									NEED		
		MAX			ALLOCATION			AVAILABLE					
		A	B	C	A	B	C	A	B	C	A	B	C

Banker's Algorithm: Example

Q3: Is the system in a safe state? Why?

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1				0	0	0
	T_1	1	7	5	1	0	0				0	7	5
	T_2	2	3	5	1	3	5				1	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				2	9	9	1	5	2			

Banker's Algorithm: Example

Let's start with T_0

THREADS		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
	T_0	0	0	1	0	0	1				0	0	0
	T_1	1	7	5	1	0	0				0	7	5
	T_2	2	3	5	1	3	5				1	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				2	9	9	1	5	2			

Banker's Algorithm: Example

Eventually, T_0 finishes and releases all its resources

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	0	0	1				0	0	0
	T_1	1	7	5	1	0	0				0	7	5
	T_2	2	3	5	1	3	5				1	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				2	9	9	1	5	2			

Banker's Algorithm: Example

T_1 can't execute as it still might NEED (0, 7, 5) and AVAILABLE = (1, 5, 3)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	0	0				0	7	5
	T_2	2	3	5	1	3	5				1	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				2	9	8	1	5	3			

Banker's Algorithm: Example

T_2 can execute as it still might NEED (1, 0, 0) and AVAILABLE = (1, 5, 3)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C

	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	1	3	5				1	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				2	14	10	1	0	1			

Banker's Algorithm: Example

T_2 can execute as it still might NEED (1, 0, 0) and AVAILABLE = (1, 0, 1)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	2	3	5				0	0	0
	T_3	0	6	5	0	6	3				0	0	2
	Total				3	14	10	0	0	1			

Banker's Algorithm: Example

T_2 eventually finishes and releases all its resources

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	0	6	3				0	0	2
	Total				1	11	5	2	3	6			

Banker's Algorithm: Example

T_3 can execute as it still might NEED (0, 0, 2) and AVAILABLE = (2, 3, 6)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	0	6	3				0	0	2
	Total				1	11	5	2	3	6			

Banker's Algorithm: Example

T_3 can execute as it still might NEED (0, 0, 2) and AVAILABLE = (2, 3, 6)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	0	6	5				0	0	0
	Total				1	11	7	2	3	4			

Banker's Algorithm: Example

T_3 eventually finishes and releases all its resources

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	5	2				0	2	3
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	-	-	-				-	-	-
	Total				1	5	2	2	9	9			

Banker's Algorithm: Example

T_1 can now execute since NEED (0, 2, 3) and AVAILABLE = (2, 9, 9)

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	1	7	5				0	0	0
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	-	-	-				-	-	-
	Total				1	7	5	2	7	6			

Banker's Algorithm: Example

We have found a sequence of execution T_0, T_2, T_3, T_1 which leads to safe state!

		RESOURCES											
		MAX			ALLOCATION			AVAILABLE			NEED		
		A	B	C	A	B	C	A	B	C	A	B	C
THREADS	T_0	0	0	1	-	-	-				-	-	-
	T_1	1	7	5	-	-	-				-	-	-
	T_2	2	3	5	-	-	-				-	-	-
	T_3	0	6	5	-	-	-				-	-	-
	Total				-	-	-	3	14	11			

Summary

- Deadlock → a situation in which a set of threads/processes cannot proceed because each one requires resources held by another

Summary

- Deadlock → a situation in which a set of threads/processes cannot proceed because each one requires resources held by another
- Detection and Recovery → recognize deadlock after it has occurred and break it

Summary

- Deadlock → a situation in which a set of threads/processes cannot proceed because each one requires resources held by another
- Detection and Recovery → recognize deadlock after it has occurred and break it
- Prevention → design resource allocation strategies which guarantee at least one of the 4 necessary deadlock conditions never holds

Summary

- Deadlock → a situation in which a set of threads/processes cannot proceed because each one requires resources held by another
- Detection and Recovery → recognize deadlock after it has occurred and break it
- Prevention → design resource allocation strategies which guarantee at least one of the 4 necessary deadlock conditions never holds
- Avoidance → runtime checks to avoid deadlock online

Summary

- Deadlock → a situation in which a set of threads/processes cannot proceed because each one requires resources held by another
- Detection and Recovery → recognize deadlock after it has occurred and break it
- Prevention → design resource allocation strategies which guarantee at least one of the 4 necessary deadlock conditions never holds
- Avoidance → runtime checks to avoid deadlock online
- In practice, most OSs don't do anything and leave it all to applications
